JOHN DUNSTABLE AND LEONEL POWER: A STYLISTIC COMPARISON

Beverley Gaye Smith

SUMMARY

This thesis is an attempt to define and compare the styles of two English composers active early in the fifteenth century - John Dunstable and Leonel Power. The two are commonly confused in the surviving manuscript sources of their music and to date there has been no reliable method for the determination of authorship in cases of conflicting attribution.

Part One of the investigation consists of an analysis of works which bear uncontradicted ascriptions. The information is used to set up a database for each of the composers. The analysis is largely computer-aided and covers aspects of form, pitch, range, chord structure, melodic structure, speed, text setting and cadence progressions.

Part Two compares a variety of uncertain works against the databases and in each case employs the statistical method of Discriminant Analysis to calculate which of the two composers is more likely to be responsible for the composition. In all of the six pieces with ascriptions to both men, the results indicate the likely author to a probability of over 1.00. The data are also used to assess many anonymous pieces and mass pairs.

JOHN DUNSTABLE AND LEONEL POWER
A STYLISTIC COMPARISON

ACKNOWLEDGEMENTS

Many people and institutions have been of assistance in the preparation of this thesis. In particular, I wish to express my gratitude to:

My husband who has patiently looked after himself, the house and the children for the last two years.

Dr. Alan Brown for his supervision of the project, his help in transcribing the Kyrie Lux et origo, his time in carefully reading my drafts, his continuing interest and his valuable comments.

Tom McCanna for his help in the library and for his translation of foreign articles.

Dr. P.G. Blackwell for his advice on statistical procedures.

The governors of the Sheffield Grammar School Exhibition Fund for providing grants to cover two years' university fees.

The Petrie Watson Committee for funding a period of study in Italy.

The Biblioteca del Seminario Maggiore, Aosta; the Civico Museo Bibliografico Musicale, Bologna; the Biblioteca Universitaria, Bologna; the Biblioteca Nazionale Centrale, Florence; the Biblioteca Estense, Modena; the Castello del Buon Consiglio, Trent and the Museo Diocesano, Trent for allowing me to consult musical manuscripts.

AIMS OF THE STUDY

During the fourteenth century, the seeds of a great social movement had been sown, that of Humanism, which was to dominate the Renaissance period of European history. The essence of this movement was a shift of emphasis away from the supreme power of the Church and towards man as the centre of society, bringing long-established religious ideals into question. A rift between the serious and popular aspects of life began to deepen; sacred and secular music started to separate in function. The Arts in general were no longer regarded solely as aids to worship but as sources of pleasurable experience. Sacred music itself responded to the spirit of the times and became designed more to appeal to the senses than ever before.

An important sequel to this movement was that in the early fifteenth century increased recognition was given to music and musicians by the ruling monarchs. At least one King Henry was a composer in his own right.[1] Henry IV expanded the Chapel Royal and took a keen interest in music.[2] With Henry V, musicians were recorded separately from secretaries for the first time. The little notated music which has survived from prior to this era was largely anonymous, but now more attributions to named

---

[1] For the argument in favour of Henry V see Margaret Bent: 'Sources of the Old Hall Music' in PRMA, vol.94 (1967-8), pp.23-35.

[2] Brian Trowell: 'King Henry IV, Recorder-Player' in Galpin, vol.10 (1957), p.83.

composers began to be recorded, those in the Old Hall manuscript (OH) being among the earliest English examples. This development allows historians a first glimpse of personal compositional styles.

The whole subject of the evolution of composer individuality is a complex one.[3] The growing interest in the composer as a creative individual did not always necessarily coincide with the formation of individual styles. In fact, the known output of early composers is often impossible to separate stylistically from the whole, relatively narrow body of contemporary music with which it shares the same fundamental characteristics. To some extent this is also true of the fifteenth century, yet just enough differentiation of style might exist for modern analytical methods to break through the curtain of anonymity. Our modern preoccupation with composer identity motivates the search for authenticity and the tools now exist to allow the process of unravelling the associated problems to begin.

The raw materials of the present study, taken from English music of the first decades of the fifteenth century, are found sometimes in insular sources but due to the loss of much material, presumably during the Reformation, mostly survive only on the Continent, especially in northern Italy. False and contradictory attributions abound in this corpus, probably the more so

---

[3] See for example Ludwig Finsher: 'Die "Entstehung des Komponisten": Zum Problem Komponisten-Individualitat und Individualstil in der Musik des 14.Jahrhunderts' in IR, vol.6 (1975), pp.29-44.

because the music was copied 'second hand'. Sometimes it seems that the new habit of naming a composer was, in itself, more important than the accuracy of the attribution. Though much work has been devoted to studies of the manuscripts and transcription of their contents, the full potential of analysis in addressing problems of authorship has not yet been realized.

Trowell and Hughes have conducted excellent surveys of English music in their PhD theses,[4,5] and Bent has produced a comprehensive study of one composer, John Dunstable,[6] but these authors have stressed the need for further investigation. When discussing the problem of the conflicting ascription of music in different manuscripts, Hughes suggested that more analysis should be undertaken of the respective styles of different composers. Bent has stated:

> How can we know whether an ascription is correct? We are largely at the mercy of general impressions and detailed case histories of individual pieces for judgements about the reliability of manuscripts.[7]

The relative accuracy of different manuscripts has sometimes been the only criterion for allocating authorship in disputed cases, for example by Bukofzer in the commentary to the collected edition of *Dunstable's*

[6] Margaret Bent: Dunstaple (London, 1981).

[7] Ibid., p.7.

works (MB8). However, this policy is questionable, especially as manuscript accuracy is difficult to assess, making the arguments to some extent circular. Much more satisfactory would be an allocation on a stylistic basis, though to date not enough data have been available to make this possible. To quote again from Bent:

> Just how little we know about (his) style ..... can be seen when we try to answer a question such as: Is this work an authentic composition of Dunstaple? ..... We do not know enough even to distinguish the work of one English composer from another on grounds of style, although the general features of 'Englishness' can be safely described and distinguished from foreign work.*

She bypasses the problem of correctness of ascription and treats most of the music in the collected edition as being by Dunstable, though many of these works bear conflicting or dubious attributions. This present study takes up the problem highlighted by this scholar and others. Its primary aim is the detection of personal compositional traits.

Though over thirty English composers are named in contemporary manuscripts, the majority are linked with too few works to provide enough material for a meaningful statistical analysis of their styles. More music has survived which is attributed to John Dunstable and Leonel Power than to any of the other composers, and a substantial number of conflicting ascriptions concern these two men. Their styles will therefore be the central theme of this thesis.

---

* Ibid., p.9.

The project has been approached in two stages. Part One is an attempt to define and contrast the styles of the two composers through an analysis of their surviving music. Part Two uses the information thus obtained to assess many other pieces whose authorship is, for some reason, dubious. Few of the areas to be investigated are novel. In fact, as many ideas as possible have been gleaned from suggestions by other writers for possible forms of analysis. These are explored in greater detail to ascertain their value and a summary of the worth of each particular technique is given; some methods prove useful, others not. On occasion, a line of enquiry sheds light on related topics, such as chronology and the development of style.

The central task of separating Leonel and Dunstable is not an easy one; the number of investigations which yield no useful information certainly outweighs the number of successful ones, although it has been considered necessary to report on all the methods employed, successful or not, as this may be of help to future workers. A topic which has been studied for many months and concerns a large body of data might yield only minute differences between the composers. Those differences which are extracted are often obscure or concern trivial aspects of composition. This is a measure of the closeness of the two styles. Often, a computer will be used to gain the necessary accuracy to separate such outwardly similar groups of compositions. A second, but important, aim of the thesis is therefore an assessment of

the role which the computer can play in musical analysis. No apology is made for this method of research, which is now gaining acceptance in musical circles, and its validity will be discussed in detail later.

In the past, several computer-aided studies have been performed on early music subjects.* Most of these have been experimental in nature and/or limited in scope. Often, a promising line of investigation has not been followed to fruition. The present study aims to be a larger and more detailed computer-aided investigation of a single corpus of music than has been conducted previously.

HISTORICAL BACKGROUND

The importance of English music in the early fifteenth century and its reputed influence on Continental style is well known. Most accounts of this period in musical history begin with a description of the various references to Dunstable by Tinctoris, Martin le Franc and John of Wheathampstead which testify to his prominent position. It is surely not necessary to reproduce these again. Suffice it to say that this composer was highly regarded by his contemporaries.

The name of Dunstable is reasonably well known today, not only due to this high regard, but also because of the large quantity of his music which has survived. However, the features most admired and copied by Dufay, Binchois and others were present in the music of the English school in general and were evident in the OH manuscript, which predates Dunstable. This musical source attributes more pieces to the composer Leonel (Power) than to any other single person. Therefore, his name also is becoming increasingly recognized and associated with this historical period.

Such references as remain, however, are of little help in tracing the careers of these men. Most composers of the time remain enigmatic figures. The few known facts have been descibed by other writers.[10] Here, therefore,

---

[10] Roger Bowers: 'Some Observations on the Life and Career of Lionel Power' in PRMA, vol.102 (1975-76), pp.103-127; Margaret Bent: Dunstaple, (London,1981), pp.1-4; Margaret Bent 'Dunstable, John' in Grove, vol.5 (1980), p.720 and

the main points will be recounted only briefly for the sake of completeness and in order that a few personal observations can be made.

The first observation concerns Dunstable's name. In an age prior to standardization of spelling, it appears variously in the manuscripts as Dunstable, Dunstaple, Dunstabell, Dumstable etc. It is this writer's opinion that Bent is too pedantic in her insistence upon 'Dunstaple' in preference to the more traditional 'Dunstable', especially as at least seven other variants are recorded, and despite the fact that the Bedfordshire town where the composer's family name most probably originated has become 'Dunstable' in modern usage. Even her reasoning is in error in one respect. It is true, as she claims, that more than twice as many musical attributions use the spelling 'Dunstaple' as use 'Dunstable' but she fails to note that 80% of the former are in the same manuscript - ModB. It is logical to expect a single document to be more consistent in this respect than would be diverse sources, and this is borne out by the facts. Actually, more than twice as many manuscripts use 'Dunstable' as use 'Dunstaple'. Of course, the argument is further complicated by the fact that certain sources may be direct copies of others, and this could extend down to the details of spelling. Insular sources do favour 'Dunstable' and presumably these were closer to the composer himself than were foreign ones. Unfortunately,

---

Margaret Bent: 'Power, Leonel' in Grove, vol.15 (1980), pp.174-175.

there is no evidence to suggest that any autograph copy exists, and even if it did, no reason to believe that the composer himself would have always spelled his name in the same way. The most sensible procedure seems to be to continue the traditional spelling, especially as the argument is of no direct consequence to the study of the music.

It is almost certain that a grave in St. Stephen's Church, Walbrook contains his remains. The original epitaph was destroyed in the Great Fire of London, 1666, but luckily the text had been recorded. Bent gives a translation. If the wording has been transmitted correctly, we have a date of 24th December, 1453 for Dunstable's death.

On the other hand, a precise date of birth is impossible to ascertain. His earliest surviving pieces may have been composed as early as 1410 on the evidence which has been used to date the manuscripts in which they are recorded. For example, a study of OH shows that the portion containing his four-part motet Veni Sancte Spiritus was completed by about 1420 or shortly afterwards.[11] Not enough information is yet available to date any works on a stylistic basis, and unlike many motets of his Continental contemporary, Dufay, Dunstable's show little evidence of having been composed for specific occasions. Howlett has suggested that the motet Albanus roseo rutilat to St. Alban could have been composed

---

[11] Margaret Bent: 'Sources ....', pp.21-26 and Roger Bowers: Op. Cit., pp.109-110.

for the Duke of Bedford's visit to St. Alban's Abbey on the 17th June, 1426 (the saint's feast day).[12] The evidence is not solid, however. At best, then, Dunstable's birth can be placed at around 1390.

Much evidence has always pointed to a connection with the Duke of Bedford and it has often been assumed that Dunstable travelled with him to France. Recently, since the preparation of Bent's book, new evidence has been put forward by Wathey to show that he may have owned lands in Normandy.[13]

Considering the lack of information concerning Dunstable in contemporary writings, his posthumous fame was immense. By the sixteenth century, he had become a legendary figure and was even credited with the distinction of having been the inventor of counterpoint. This myth prevailed well after his music had been forgotten and even coloured his reputation amongst historians well into the present century. Bukofzer has discussed the origin and transmission of the legend.[14] The one-time belief that the composer had written a musical treatise has also now been discredited.

If the importance of Dunstable has been overestimated then it is equally true that, at least until very recently, that of Leonel has been overlooked. His

---

[13] Andrew Wathey: 'Dunstable in France' in M&L, vol.67 (1986), pp.1-31.

[14] Manfred F. Bukofzer: 'John Dunstable: A Quincentenary Report' in MQ, vol.40 (1954), pp.32-35.

compositions demonstrate a high level of skill and his output appears to have been almost as great as Dunstable's. Also, he is known to have written a musical treatise on the art of discant.

There are quite a few references indicating that Leonel's profession was that of choirmaster and that he was a layman rather than a member of the clergy. The earliest of these places him in 1419 in the household chapel of Thomas, Duke of Clarence, with whom he probably travelled to France. Following the Duke's death in 1421, there is no record of his employment elsewhere for the next fifteen years. Bowers presumes that he would have continued to work in aristocratic households, and even speculates that he may have moved into the service of Clarence's brother, John, Duke of Bedford, in which case he may have come into contact with Dunstable. In 1423 he was admitted to the fraternity of Christ Church, Canterbury, and from 1438 onwards was employed there, probably as Master of the Lady Chapel choir. He died on 5th June, 1445.

The spelling of his name to be used here, Leonel, is that most often used in the musical manuscripts and is adopted out of convenience because a discussion of these attributions is central to the thesis. Archival sources often use the English form Lionel. Bowers can offer no explanation for the fact that the composer is usually referred to by his first name,[15] though a clue might

---

[15] Roger Bowers: op. cit., p.103.

actually be held in a later discussion in his article.[14] It seems that in the Duke of Clarence's service were two other men of the surname Power. One, a singer, first name Richard, may not have joined the chapel until a later date, but it is possible that a Thomas might have been in service at the time when Leonel's first compositions were copied into OH. The use of a first name could simply have originated to avoid confusion between these individuals. This theory, however, is put forward with caution as the present writer has not had access to the relevant archive sources.

Bent puts Leonel's birthdate between about 1370 and 1385 on stylistic grounds while Bowers suggests the narrower period of 1375 to 1380 on the available biographical evidence. It is almost certain that he was an older man than Dunstable because of his compositions in the descant style and the fact that his music is amply represented in the original layer of OH.

---

[14] Ibid., p.108.

SCOPE OF THE STUDY

The first stage of this investigation (Part One) of necessity concerns only music whose composer is known with a fair degree of certainty. Ideally, two or more uncontradicted ascriptions to a work would be desirable to provide a high degree of assurance of authorship, but, of the forty-three individual compositions with uncontradicted ascriptions to Dunstable, only ten have these in more than one source. The picture is even more disappointing in the case of Leonel who has only three out of thirty-eight compositions assigned to him on more than one occasion. All works with uncontradicted attributions will therefore be treated initially as being by the named composer.

It must be accepted that some of these attributions may be erroneous. Twenty-two pieces credited to Dunstable bear a composer's name in more than one manuscript; in over half (twelve) of these cases, the names conflict. Assuming that either attribution might be the correct one, this indicates that in up to 25% of cases a single attribution could be wrong. However, it is likely that the error is not so great in the compositions chosen for study in this thesis. Almost a quarter of those in Dunstable's group have more than one ascription and many others appear in ModB, a manuscript generally regarded as reliable. Although very few of those in Leonel's group have a second attribution, this is offset by the fact that many appear in OH. Because this is an insular source it

is probably more trustworthy than foreign manuscripts copied at some removes from the composer's originals.

Of the music mentioned above, only three pieces (with attributions to Dunstable) are secular works. These are omitted from the main part of the study, mainly because two of the three bear conflicting attributions. Also, they are all atypical pieces and there is no known secular music by Leonel for comparison. They will be considered briefly in Part Two, along with all the pieces of unknown authorship. This second stage in the investigation will compare these works with the database of results obtained in Part One.

Some pieces have been paired, for various reasons, with ascribed works but bear no attribution themselves. These will be considered to be of doubtful authorship. In an age abounding in musical plagiarism, similar compositions cannot be assumed to have a common author. In fact, the greater the resemblance between a paraphrase and its model, surely the more easily the paraphrase could have been constructed by another hand. All such possible pairings will be reserved for discussion in Part Two.

THE MUSIC

All of the music to be considered in the first part of this study has at least one uncontradicted attribution to either Leonel or Dunstable. A listing appears in Tables 1-2. The numbering adopted is that used in the two main anthologies, CMM50 and MB8. To save space in tables of results, pieces are often identified only by the first word of text in the top voice and by a number. In Leonel, the numbers refer to volume one in the case of motets and volume two in the case of mass music, though at the present date this latter volume has still not been published.

The analyses have been conducted, where possible, on the transcriptions as they appear in CMM50i and MB8. The mass movements of Leonel have been taken from CMM46 or from ACM. All musical examples and quoted bar numbers are as they appear in these volumes.

CMM50i contains a disappointing lack of commentary. Also, a major omission in its layout is that of designations for voices in duet sections. Sometimes it is possible to deduce which voices are involved, sometimes not. Where possible the original manuscripts have been consulted. Any wrong allocation is unlikely to affect the analyses significantly.

Correctness of transcription in these modern collected editions will be assumed as it is beyond the scope of this project to check all the music against its manuscript sources. Minor errors in transcription would,

in any case, have little effect on the statistical evaluation of a large corpus of material.

Terms such as 'tenor' and 'contra' to describe voice parts can sometimes be misleading. In this corpus of material the cantus firmus (c.f.) can appear in different voice positions or the music can be freely composed without reference to a c.f. For the sake of clarity, therefore, the parts will usually be identified by Roman numerals, I being the highest voice, II the next highest and so on.

The positioning of the voices in the collected editions (based on the original manuscripts) is almost always a function of their pitches. Occasionally, the range of a voice gives the impression that it has been wrongly placed. Usually in these cases the ordering is correct when the average pitches of voices and their rates of movement are considered. These matters are dealt with more fully in Part One.

Sections of music for duetting voices are often analysed separately in the following chapters. Where duets are referred to, very short sections of less than four bars are usually not included (an exception being in the study of cadences) as they are too short to give meaningful results. Analyses of fully-voiced music, however, do not include these sections either.

Two pieces must be mentioned particularly as regards their duets. In Crux fidelis (MB8 no.39) the duet from b.72-106 is given in one source (ModB) to voice II rather than voice III. As the range and average pitch is closer

to that of voice III, the duet will be regarded as involving that voice.

Sub Tuam Protectionem (MB8 no.51) survives in two versions, one having a duet between voices I and III at bb.54-78, the other being fully scored at this point. There is reason to suspect that the version with duet is the original form (see pp.355-359 for a full discussion) and it is on this basis that the analyses will be performed.

THE USE OF COMPUTERS

VALIDITY

Despite the advance in computer technology over recent decades and its increasing use in many spheres of research, musicians remain, in general, wary of the medium. It is true that in the field of composition computers have found a niche, but they are rarely used by the historian. Rarely have such workers had the background of mathematical and/or scientific training which has previously been necessary to understand the possibilities of computer technology and then to convert ideas into working programmes. It has always been possible to employ a third party as programmer, but this distances the musician somewhat and makes it difficult for him to control the process. Another problem has been access to sufficient computer time for programmes to be developed. The increased power of modern computers and the advent of the personal computer (PC) have now made these problems a thing of the past. In an increasingly computer-literate society, the user-friendly PC has opened up almost unlimited possibilities for the analysis of music. It is the belief of this author that historical research will eventually be dominated by the computer.

Many have doubted the value of computer analysis. For example, in a discussion of modality, Geoffrey Nutting states:

> No doubt one could devise tabulations .... and instruct computers to report in these terms on a

> large corpus of material, but the value of such procedures is questionable..... It is therefore sensible to respect "intuition" (i.e. the verdict of the incredibly complex computer in our heads).[17]

This view underestimates the potential of computing and overestimates the power of the human mind.

Over twenty years ago Mendel experimented with computer analysis.[18] However, he remained sceptical about the value of this approach. Later, he concluded that there are two types of characteristics in music - those which can be measured by computer and those which can't, and that the computer will never be able to produce 'artistic' descriptions.[19] His second category includes subjective descriptions such as 'lively', 'sad', 'expressive', 'flowing' etc. The present writer has always felt uneasy with such descriptions. They occasionally sound impressive but often have no precise meaning and give us no idea, in the absence of a score, of how the music actually sounds. These terms very often describe not the music but the emotions of the listener. Any which do describe the music CAN be measured. No matter how poetical we wax, there is nothing in music which cannot ultimately be described in terms of pitch,

duration, loudness and timbre. We might not want to describe music in this way but this doesn't mean that it isn't possible to do so.

The music to be considered in this thesis is an ideal subject for computer analysis. It only requires encoding for pitch and duration (the only two of the above parameters transmitted in the sources). The compositions are reasonably short and consist of a standard 3 or 4 voices. That the corpus is quite uniform in style is one reason why differentiating composer styles has hitherto been difficult, but it is this same fact which makes computer analysis easy - it is so much easier to compare like with like than to compare the diverse styles which exist in later music.

If all other arguments in favour of computer analysis fail, it is worth considering that we have failed to answer certain questions concerning individual composer style and authenticity by traditional means, so we can't do any worse if we try other avenues.

ENCODING METHODS

The present author had had no previous experience with computers before embarking upon this project and was self-taught in their use, so progress was initially slow and took much determined effort. However, the end results are proof that worthwhile objectives can be achieved with the medium.

The programmes were all developed and run on a home computer with only a small memory capacity. The tasks possible within the capabilities of the equipment were therefore limited. Much time was spent modifying programmes which were too big to run. Recently, much more powerful PCs have appeared which would make a similar study far easier and capable of more depth. However, as the programming had already been written for one machine, it was not thought practical to switch systems mid-stream.

The following description of computer encoding is included for those interested. It is not necessary to read this section in order to understand the remainder of the thesis as the analyses and results are all explained in musical terms. The system was developed without contact with or reference to any previous studies and was therefore designed from scratch. The system has served its purpose well and without problems and has an advantage over the encoding methods used in some studies in that it is easily readable without translation.

A BBC model B computer with 32K of total memory was used. All programming was done in the language BBC basic. Each composition was encoded in the form of files which were stored on 5.25 inch floppy disks. Separate files were produced for each voice of a composition and another encoding all voices simultaneously.

It was decided that letters be used, rather than numbers, to denote pitches. This was to make typing in of the files easy and also to aid readability, making any errors easy to spot. For analysis purposes, the computer

can be programmed to convert these letter names into numerical values as necessary. Pitches were denoted as follows:

FF, GG, A-G, a-g, a'-g' with c=middle C.

Sharps and flats were recorded as '#' or 'b' after the letter name and included as they appeared in the main text of the editions (but not editorial musica ficta indications). Rests were denoted either as 'R' or 'r' to avoid frequent shift changes in the process of typing.

Durations were indicated as multiples of a minim length (which is usually a quaver in modern transcription). The minim was initially chosen for ease of typing as it produces fewer fractional or very large values than would other standards. Also, it is more appropriate, being a fixed duration note (the breve,for example, can be various lengths depending upon its context). Notes smaller than a minim were denoted by fractions given to two decimal places. Sometimes the values are complicated when mensurations clash and triplets abound, for example in Leonel's middle period mass movements. In these compositions, voice I is often notated in doubled values compared to the other voices. Here, the encoded values are fractions of a notated semibreve. In CMM46, some of Leonel's pieces in perfect prolation are transcribed with a breve equal to a modern minim, resulting in the need for large numbers of triplets. These have been encoded treating the breve as a

dotted minim to correspond with the treatment of similar pieces in CMM50i.

Single voices were encoded thus: for example the beginning of Dunstable's Kyrie MB8 no.1, voice I:

/f4 a'1 bb'1 /g2 bb'4 etc.

'/' signifies the beginning of a bar in the edition. This has no significance in the analyses and is there only to make locating sections of code simpler.

A computer programme was written to combine the separate voice files into a single 'harmony' file. Each new chord formed by the entry (or dropping out) of one or more voices was encoded separately. The lowest part appears first, voices being separated by commas. Voices not entering with a new note but holding the previous one are prefixed 'h'. The beginning of the same Kyrie becomes:

```
/F,c,f,2
hF,d,hf,1
hF,e,hf,1
hF,f,a',1
hF,hf,bb',1
/bb,d,g,2
hbb,r,bb',2
d,f,hbb',2      etc.
```

The process of typing in and saving all the information onto computer discs in itself took several months. For the 114 compositions to be studied, over 100,000 notes and 60,000 chords needed to be encoded, recorded and checked.

Mendel admitted to having problems with errors in his coding and no doubt the same difficulty has plagued more recent workers. It has been relatively easy in the present study to detect errors. As the BBC computer has built-in sound capabilities, a programme was written to read the coding and play it back. Most errors in pitch were therefore picked up at the single voice stage. Any errors in duration escaping detection here were picked up when the voices were combined as they simply wouldn't finish together. The BBC is capable of playing on three channels simultaneously, so the full harmony could also be checked. This proved to be a good way of hearing and getting to know unrecorded music. Unfortunately, four-part music could only be listened to three voices at a time.

PART ONE

GENERAL STRUCTURE AND STYLE

English music surviving from the early fifteenth century is mainly sacred in function. It consists of settings of mass movements and other texts, mainly antiphons. This latter group of pieces will be referred to here under the wider heading of 'motets'. A three-part texture is the norm, with occasional pieces in four parts.

It became evident early in the study that the results of analyses were affected by the type of composition. Two categories, those of English descant and isorhythm, are particularly noteworthy. Both styles have often been discussed so only a brief description need be given here.

ENGLISH DESCANT

The term 'descant' is confusing in that it has been used for different purposes. It is essentially a method of harmonizing a plainsong in a note-against-note, as opposed to melismatic, style. It has been used to describe both improvisatory techniques and composed music, some of which will be discussed in this thesis. The main features of the composed style of the late fourteenth century are:

i) Employment of a cantus firmus chant, usually in the middle voice of three, often transposed up by a fifth or some other interval. The plainsong is unornamented and moves in uniform long note

values.

ii) Largely homorhythmic writing with voices equal in character and with little decoration.

iii) Different voice ranges with little overlapping of parts.

iv) No changes in mensuration and often in perfect prolation.

v) No resting of parts.

vi) No contrasting duet sections.

vii) Quite short compositions.

The pure style was falling out of use by the fifteenth century, although examples survive by Leonel. It has been suggested that such pieces may have been composed early in his career and, although no firm datings are possible, this is likely because of their inclusion in the Old Hall manuscript which has a largely fourteenth-century repertory. His simplest use of the form is seen in the Sanctus, CMM50ii no.1. More often, he expands its boundaries by making the rhythm more adventurous, ornamenting the plainsong and putting it into the highest voice or by employing changes in mensuration and texture. It would perhaps be a misuse of the term descant to include all these more advanced pieces under the heading. Hamm classed all Leonel's (presumably) early plainsong harmonizations together in the collected edition, calling them Group I.

ISORHYTHM

In a complete contrast to the descant style, isorhythm is based on the Continental practice of employing voices of unequal character, though often crossing in pitch. Here the disparity is rather extreme with a very slow-moving tenor. This voice is based on a repeated talea (fixed rhythmic pattern) and often a color (fixed melodic pattern) and so in reality can be not only isorhythmic but also isomelic. Fourteenth-century English examples exhibit a variety of forms, some quite irregular, but in Dunstable the technique was refined and contained within fairly strict outlines. Generally his isorhythmic works consist of three sections where the tenor is stated in progressive diminution in the ratio of either 3:2:1 or 6:4:3, each containing two statements of a talea, the second combined with a different color. The upper voices sometimes also employ rhythmic repeats.

Leonel wrote little (surviving) isorhythmic music and when he did employ the technique it was not in the 'classical' form described above. Taken alongside the fact that Dunstable did not compose in simple descant, this means that there is quite a disparity in their general styles; 33% of Leonel's and 30% of Dunstable's three-part compositions are quite distinct. However, it is perhaps no coincidence that none of the compositions of disputed authorship is in either of these categories. Therefore, although the two styles will sometimes be

analysed in this thesis as being interesting in their own right, data on them are not admissible in comparisons intended to allocate the disputed compositions between the two composers. Unless otherwise stated, and to save much repetition, the measurements and comparisons to be made in the following chapters are based on those pieces which fall in the common ground and not on those in the descant and the classical isorhythmic styles.

Hamm actually classified Leonel's music into three groups which Bowers has tentatively linked to the three phases of his professional career.[20] The speculation that he could have been in the same company as Dunstable during his middle period is interesting as it is amongst pieces in his second style group that confusion over authorship between the two men exists. It is also within this group of compositions that his style most resembles that of Dunstable.

Hamm's third group consists of a small number of slightly more experimental pieces which could possibly have been written during the composer's employment at Canterbury. This would have been a period of isolation from outside influence which would once again preclude confusion with Dunstable. These works have nevertheless been included in the comparison calculations as no datings can be certain and they are not altogether removed from the style of the second group, usually giving similar test results. To exclude them would seriously diminish the

---

[20] op. cit. p.123.

amount of material included for analysis compared with that by Dunstable and the statistical comparisons between the two would be less profitable.

It is difficult to draw conclusions about compositions written for four voices as few of these survive, making statistical analysis not very meaningful. Also, all but one of Dunstable's four-part pieces are isorhythmic and so not directly comparable with those of Leonel. None of the works with conflicting attribution is in four parts so, although a cursory glance will be cast on these pieces, they will also not be included in the measurements and comparisons unless expressly stated.

PITCH AND RANGE

Several topics will be considered in this chapter including the range of whole compositions and individual voices, average voice pitches, the distances between voices and the clef combinations appearing in the original manuscripts. All this information for the pieces in the database is contained in Appendix 1.

Although measurement of intervallic distance in terms of a semitone is normally the most accurate method, this is inappropriate in the present study for two main reasons. First, the music with which we are dealing is not essentially chromatic. Contemporary theoretical treatises suggest that it was visualized primarily in terms of the diatonic scale. Secondly, uncertainty may arise in the treatment of chromatic alteration of notes as there is still no complete understanding of the processes involved in the musica ficta of the period. Ranges are therefore described in terms of the number of scale notes they include without the unnecessary complication of defining interval species (major, minor etc.). A unison is described as an interval of 1. Distances between voices are sometimes negative, indicating that they are in the 'wrong' pitch order.

Bent has recently suggested a new interpretation of the contemporary rules for musica ficta. She believes that the melodic inflections which they produced during the course of a piece might sometimes have led to alterations in the sung pitch of the remaining passages,

causing a shift in the total pitch of the music.[21] Such instability would be difficult to take account of here, so all measurements quoted are in terms of the notated pitch.

It might seem unnecessary to employ a computer to measure range. However, in the circumstances of the music already being encoded, this seemed the logical option and had the advantage of accuracy. The difference between the two composers is small and only one or two errors could affect the conclusions of the testing. CMM46 does give ranges for voices at the beginning of each composition. Whilst being accurate enough to be of use to performers, it was discovered during the course of the present study that these ranges are often slightly wrong. This illustrates the ease with which mistakes of observation might be made in very simple matters.

Table 3 summarizes the voice ranges in three-part compositions. Leonel's descant compositions have quite narrow voice ranges. The most common span covered is an octave and none exceeds a ninth. Excluding the descant pieces, there is little difference in the average range for voices composed by Dunstable and Leonel. For both, the most common span is a tenth. Leonel, however, shows less variation in range, all but one of his voices falling within the limits of an octave and an eleventh.[22] Ranges outside these limits would favour Dunstable as composer.

---

[21] Margaret Bent: 'Diatonic Ficta' in EMH, vol.4 (1984), pp.1-48.

[22] The exception is in the mass on Alma redemptoris which shows other features anomalous to Leonel's style and is investigated in this respect in Part Two.

	8	3	43		
	9	4	57	1	20

Compositions in four parts have, on average, slightly smaller voice ranges than those in three, the most common being a ninth as can be seen from Table 4. Dunstable's music again exhibits a wider variation of ranges, although this is mostly due to the fact that all but one of his four-part works are isorhythmic and have narrow tenors based on only a fragment of plainsong.

Dunstable most often uses an overall range of two octaves for whole three-part compositions whilst Leonel favours one degree less (Table 5). Any piece employing over two octaves is more likely to be by Dunstable. Surprisingly, the overall range is smaller for pieces in four voices than for those in three. This is only in part due to the narrower individual voice ranges and mostly caused by a greater overlapping of pitch in four-part textures.

Assuming that each line was intended to be sung by more than one voice at a time, some duet sections of the period might have been intended for soloists. Some are actually marked with the indication 'unus' or 'duo'. If solo rendition was intended, duet sections might be more virtuosic in nature than the remainder of the music. A comparison of the ranges of duet passages and fully-voiced sections of music has been carried out to test this hypothesis. In fact, no overall increase in range can be detected; the two-part portions exhibit a slightly smaller mean range and a larger spread of values, as would be expected from any sampling of brief sections of a piece. Many duets are quite short and often happen

mid-phrase. These are unlikely to be sung effectively by reduced forces. Others are more lengthy, structural in nature, often comprising a separate section of the work and are sometimes indicated as duets in the manuscripts. It is more likely that these could have been performed by soloists. However, their ranges merely approximate more closely to those of the full sections than do those of the transient duets.

A by-product of these calculations produced an interesting difference between the two composers' handling of duets. Where they do vary, the ranges of duets are usually only one scalic degree larger or smaller than full sections of the same piece. When all the duetting voices are taken into account, those of a composition by Dunstable are more likely to be narrower, and those of one by Leonel to be wider in range:

	narrower		equal		wider

Dunstable non-iso	9	53	5	29	3	18
Leonel non-descant	3	21	3	21	8	57

The pitch of duet sections is often shifted slightly. Upper voices tend to shift lower and lower voices higher. This is unlikely to imply increased virtuosity but rather functions to bring the duetting voices closer together. The two composers show no great difference in this respect.

Distances between voices could be calculated in many ways. It was decided to make two calculations based upon

the distance between the lowest notes and also the highest notes in each pair of voices. These distances can be compared with the clefs employed.

Clef combinations give a rough idea of voice spacing without the need for time-consuming calculation. Table 6 shows those to be found in the works of Dunstable and Leonel. The few F-clefs which appear have been converted into the corresponding C-clefs to make comparisons easier. Any changes in clef during the course of a piece are not dealt with as the modern editions do not make note of them.

Hughes has speculated that different arrangements of clefs may imply certain transpositions or even key signatures,[23] a theory which would be difficult to prove. However, Dunstable's Gloria and Credo, MB8 nos.15-16, are interesting. They are copied consecutively in Tr92 and based on the same tenor (Jesu Christe Fili Dei), so are obviously intended to form a pair. The Gloria has a clef arrangement C3-C5-C5 and the Credo with noticeably higher tessituras in voices I and II has an arrangement C2-C4-C4. Related mass movements of the period, some of which are discussed in Part Two, tend to have the same or similar ranges. The top two voices in the Gloria have a one flat signature while those in the Credo do not, though Bukofzer supplied an editorial key signature for the latter to make the movements correspond. The cantus firmus in voice III,

---

[23] Andrew Hughes: 'English Sacred Music (Excluding Carols) in Insular Sources, 1400-c1450' (diss. University of Oxford, 1963), p.450.

however, is untransposed and at the same pitch in both cases. It seems unlikely that the chant would have been sung transposed in one movement and not in the other. There is also support for the differences in key signature as the music stands, at least in voice II; the lower range of this voice in the Gloria means that it sometimes supplies a low B underneath the chant which necessarily needs to be flattened, whereas the situation does not arise in the Credo. Arguments can therefore be formulated both for and against transposition in this case.

Leonel's early pieces usually employ a different clef in each voice, reflecting the separate ranges of the parts in the descant style. In non-descant music, over 80% of the three-part works of both composers employ clefs a fifth apart in voices I and II and the same clef in voices II and III eg. C1-C3-C3. (Leonel is just as consistent in using a C1-C1-C3-C3 type pattern in his four-part works, though Dunstable is more variable.) The most common distances between the lowest notes of voices fit this scheme perfectly; a fifth between the top two and unison between the bottom two (Table 7).

Distances between the highest notes are more variable (Table 9). The most common distance between voices I and II is still a fifth but between voices II and III is a second or third. This is a consequence of the fact that voice III usually has a narrower range than the other voices, but it is interesting that this does not so often influence the position of the lowest note. Highest pitches are less fixed than the lowest and this extends to

the frequency of their appearances. In voices II and III, there is often a nominal 'lowest' pitch which is frequently sung but rarely exceeded whilst highest pitches regularly appear only once or twice in a piece. This observation prompted a more detailed examination of the frequency at which different pitches occur - a subject which will be dealt with later in the chapter.

The position of a voice in a composition is usually a reflection of its pitch. Sometimes, however, the voices appear to be in the wrong order when their ranges are considered, producing a negative value for the distances between voices. In Dunstable's Sancta Dei (MB8 no.47) voice III moves higher than voice II. The same incongruity is also true of voices I and II in Leonel's Gloriose Virginis (CMM50i no.12) and the Sanctus (CMM50ii no.21). Similarly, voice II in Ibo michi (CMM50i no.24) and the Credo (CMM50ii no.19) moves below voice III. To check the validity of the ordering of these voices, their average pitch was calculated. This being quite a complicated task, the help of the computer was needed.

First, all pitches were assigned a numerical value. The lowest pitch employed in this corpus is FF (the second below middle C) and this was therefore designated '1':

FF	GG	A	B	C	D	E	F
1	2	3	4	5	6	7	8
G	a	b	c	d	e	f	g
9	10	11	12	13	14	15	16
a'	b'	c'	d'	e'	f'	g'	
17	18	19	20	21	22	23	

Using these values, the mathematical mean was calculated for all the pitches in each part, allowing for the different lengths of note. The exact mean always falls between notes of the scale and must therefore be quoted in its numerical form. A mean of 10.50 would indicate an average pitch midway between the notes a and b. The calculation was also performed for two-part and three-part sections in isolation, although the usefulness of the information so gained was limited. In differentiating Leonel and Dunstable, no extra advantage was gained over considering the ranges of these sections, so it was not thought necessary to include the results in Appendix 1.

It can be argued that this method does not give an accurate measure of pitch 'as it is heard' because it does not take into account the different spacings of the notes of the scale. However, it is the only method which avoids the problems which would be associated with accidentals and ficta in a system based on the semitone. Also, it conforms with the contemporary view of pitches in terms of the scale and gives a measure of pitch 'as it is written'.

In all the cases of 'wrong' ordering of voices mentioned above, the mean pitch agrees with the arrangement as given in the manuscripts. However, in two four-part pieces, Preco preheminencie (MB8 no.29) and a Sanctus (CMM50ii no.7), voice IV is markedly higher in both range and average pitch than voice III. A possible explanation of this placing was to allow the cantus firmus tenor to appear at the bottom of the texture. However, it

must be mentioned that in a similar motet, Salve scema (MB8 no.30), the tenor is placed at position III.

Bent has commented on Leonel's preference for relatively low tessituras, giving as an example his Quam Pulchra, CMM50i no.26,[24] and it was hoped that this might be a useful characteristic in differentiating his style. However, this piece was found to be an exception, rather than the norm. In fact, there is little difference between the mean pitches in Dunstable and Leonel. Combining all the results to give a mean of means (!) and mean distance between means gives the following. The measurement for all voices combined is probably the best guide to overall tessitura.

	Dun iso	Dun non-iso	Leo desc	Leo non-desc
I	15.09	15.37	14.50	15.00
II	10.57	11.16	11.28	11.14
III	9.77	9.69	8.18	9.7
All Voices		12.27		12.09

From these values, the average distances between voices can easily be calculated. The spacing in descant pieces approximates to three scalic steps (a fourth) between each voice pair. In non-descant compositions, the distance between the top two voices is approximatately four scalic steps (a fifth), as would be expected from the most common clef arrangements. That between the lower voices is almost a step and a half (over a second), though these are almost always notated in the same clef. In Dunstable's isorhythmic motets, voice II often crosses the

---

[24] Margaret Bent 'Power, Leonel' in Grove, vol.15, p.177.

slow moving voice III to effect a more active bass line. This is reflected in the closer average pitches of these voices.

	Dun iso	Dun non-iso	Leo desc	Leo non-desc
I/II	4.52	4.21	3.22	3.87
II/III	0.80	1.47	3.10	1.35

Range analysis can be useful in the assessment of different manuscript versions of the same piece. The case of Dunstable's Sub tuam protectionem (MB8 no.51) will be dealt with in Part Two. In his Sancta Maria (MB8 no.49) the duet from b.40 to b.61 is given in one source (Tr92) to voice II and in the other sources to voice III. The mean pitch and range of the music are actually closer to those of voice II. In only one other case of Dunstable, a Sanctus (MB8 no.13), does the mean pitch of a voice III duet overlap the mean pitch of voice II, although in this piece the range of the duet is closer to that of voice III.

In the similar case of Crux fidelis (MB8 no.39), the lower duetting part from b.62 to b.106 is given in one source (ModB) to voice II, while the other sources give the same material to voice III. The mean pitch of this section lies almost midway between those for the two voices. The range is slightly closer to that of the tenor, though, agreeing with the majority of the manuscripts. Also, it is more likely that the pitch of III would be raised to bring it closer to I than the case if the pitch of II was lowered taking it further away from the other duetting voice.

PITCH DISTRIBUTION

As mentioned earlier, the rates of occurrence of various pitches have been investigated. The computer was used to count the number of times each pitch is used in each voice of a composition and also for the voices in combination. The results were calculated both in terms of frequency and duration of occurrence. Unfortunately, the findings did not help in the differentiation of Dunstable and Leonel's styles, so will not be recounted in full, but some observations are worthy of mention. Dunstable's Sanctus, MB8 no.6, has been chosen to illustrate the general patterns found in this corpus. The results for this composition have been expressed in graphic form in figures 1-4. The second graph in each case shows values linked to duration. There is some variation from piece to piece, but most have a similar structure.

Voice I, being the most purely melodic in function, generally shows a normal distribution of pitches. The bell-shaped spread of results is common in statistical sampling, produced by random variation in a population. The most frequent pitches are those in the centre of the range, with a gradual falling off of values on either side. In voice II the distribution is biased towards pitches higher than the centre of the range. There is usually a gradual falling off to the top end of the range, similar to the shape of voice I, but the opposite end is more drawn out, with the bottom few notes all appearing with a similar low frequency. The graph for voice III is

usually much flatter, with less variation in numbers of pitches. There is a gradual falling off at the top end, but much less at the bottom, with the lowest pitch often as frequent as those mid-range. Though voices II and III often share the same range, their average pitches are usually different, and this is illustrated by the lop-sided distribution in each case.

Sometimes, certain pitches are more prominent than would be expected in a normal distribution. Figure 5 for voice I of Dunstable's Salve regina, MB8 no.46, shows a bias towards notes of the C triad. This could be seen as a development towards a tonal centre. However, the different voices in a composition sometimes show different prominent pitches. Also, no definite pattern can be found in the linking of prominent pitches to key signatures.

The overall employment of pitches within a composition can be seen in figure 4, for the Sanctus again. Here, the voices are combined and the letters denote not absolute pitches but pitch names, all occurrences of 'a' at any octave being combined under one heading. In this case, the second graph expressing durations gives a more realistic picture, as the number of notes varies between the voices. If the choice of pitches were random, this graph would be flat; in practice it never is. The 'c' pitch is usually the most prominent, but sometimes this position is taken by the 'f' or 'g'. There is some bias towards 'f' in compositions with flat key signatures, but this is not universal.

In contrast, 'b' is always reduced compared with the

other pitches. Being the least stable pitch, both in its position as leading note in the scale and its fluctuation between flat and natural, it is employed less often than the other pitches and rarely for notes of long duration. Its frequency is often depressed below the line of normal distibution on the single voice graphs. The pitch 'e' is often also depressed, most often in pieces with flat signatures.

It would be an interesting exercise to try to link these different patterns of pitch prominence with the various modes and to consider this information alongside the cadence pitches of pieces. This, however, would be quite a digression from the purpose of this thesis and will be reserved for another time and place.

The subject of pitch cannot be left without a mention of accidentals. Their frequent appearance in Leonel's music has sometimes been noted, but this cannot serve as a marker of his style. There is no evidence as to whether the additions were indicated by the composer and there is every reason to assume, due to variant readings in different manuscripts, that their presence or absence depended more on the habit of the scribe than that of the composer. Continental sources often omit accidentals present in insular manuscripts and this could account for the discrepancy between levels in the two composers, a higher proportion of Dunstable's works having survived abroad.

TIME AND SPEED

Mendel may have been the first to suggest using the computer to calculate average note values, although Wegman has used the idea to compare Masses written over a period of time,[23] and also as a marker of composer individuality in the context of Ockeghem's authorship.[24] He has suggested that his methods may be of value in other problems of authenticity. Their use will therefore be investigated in this chapter.

In the first-mentioned study Wegman calculated the average note length in the combined upper voices of the compositions. It has not proved possible to duplicate his figures. He does not give details of how the averages were calculated or reveal whether a computer was used; such a task completed 'by hand' would be subject to error. Even with the advantage of computer analysis, however, different readings and editorial decisions can affect the result. For example, in Dunstable's Credo and Sanctus on Da gaudiorum premia (MB8 nos.17-18), two editions give conflicting interpretations of the length of the final notes in each section of music, leading to about a 3% difference in the result. For this reason, giving results, as Wegman does, to three decimal places seems

---

[23]Rob C. Wegman: 'Concerning Tempo in the English Polyphonic Mass, c.1420-70' in Acta Mus, vol.61 (1989), pp.40-65.

[24]Rob C. Wegman: 'An anonymous Twin of Johannes Ockeghem's 'Missa Quinti toni' in San Pietro B 80' in Tijdschrift van de Vereeniging voor Nederlandsche Muziekgeschiedenis, vol.37 (1987), pp.28-30.

to have no value. One decimal place is probably sufficient.

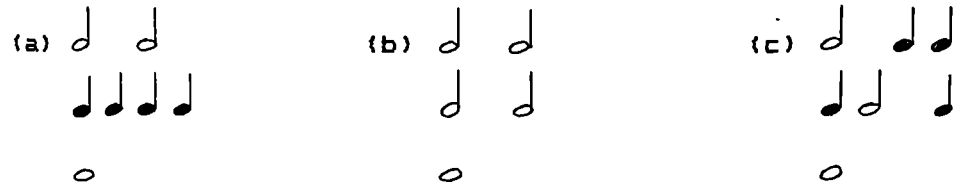
Initial calculations of average note length for this study gave such a large variation of results that this method of analysis was almost abandoned. However, various factors were found to be affecting the outcome. For instance, pieces of a highly sectional nature with frequent longs marking the close of each section would produce artificially high figures for note lengths. To remedy this problem, the process was repeated, this time eliminating end-of-section longs from the calculations. This was a time-consuming process as the computer could not distinguish between these longs and ones which occurred mid-section, but the results, once achieved, were more realistic.

Also, to obtain meaningful results, not only must sections of compositions in different mensurations be treated separately, but so must those with different voice combinations, as note values tend to be shorter in duets (either to compensate for the thinner texture or possibly to allow for greater virtuosity if the duets were sung by soloists).

Allowing for these factors, fairly consistent results can be produced. In view of this and the fact that use of the computer ensures that the results are as accurate as possible, it was thought valid to present them to two decimal places.

Combining the upper voices to give a single result does not take into account the fact that these voices vary

in character and that the lowest voice is sometimes also quite active. One could treat each voice in a composition separately, but this would provide a confusingly large number of results, especially for music of a highly sectional nature. Another method suggested itself which would produce a single result for all the voices in combination and was ideally suited to the musical coding used in this study. An 'average chord length' would measure the rate of change of chord formations in the music and could be conducted on the harmony files already in existence for each composition. These list each successive note combination formed as the music progresses (see p.34). Average chord lengths in the following short examples would be one, two and one crotchets respectively.



A sample of pieces was treated in the one-voice-at-a-time way to test the validity of this combined-voice method. While the former method gives higher results, the two sets of figures obtained were roughly in proportion. The latter method, as well as being less time-consuming, also provides a more realistic measurement of the activity of a piece as apparent to the listener.

Wegman dealt only with the O and C mensurations and gave his figures in terms of a semibreve length. Here,

the minim length was considered more convenient to deal with because in most modern transcription it is represented consistently as a quaver, whereas the semibreve may be represented as a crotchet (in imperfect prolation) or dotted crotchet (in perfect prolation). This is not intended to imply minim equivalence in performance terms; the means of representation is not important so long as it is used consistently and like is only compared with like.

Semibreve equivalence was, though, probably never admitted as a possibility by contemporary theoreticians, who were divided between either breve or minim equivalence.[87] As a by-product of this present study, some insight has been gained into the 'equivalence' question and this subject will be discussed shortly.

Tables 11 and 12 set out the average chord lengths for the music of Dunstable and Leonel. All portions of music using simultaneously combined signatures have been excluded from the calculations, except in the isorhythmic motets where the tenor moves in such long values that the outcome of chord length is not affected.

The figures for the two composers are largely indistinguishable. Both are quite variable, covering a similar range of values. Despite the large amount of time devoted to this study of chord lengths, the only fact emerging which helps in the central task of style

differentiation concerns duet sections. It was noticed that many of Dunstable's duet sections have average chord lengths longer than fully-scored sections in the same mensuration. This is most apparent in his non-isorhythmic motets, where it happens in nine out of seventeen pairs (just over half) of measurements taken. In Leonel's motets, on the other hand, it happens in only one of eight pairs of measurements. The presence of this feature in a disputed work (especially a motet), therefore, suggests Dunstable as the more likely composer. The above finding demonstrates that duets in Dunstable are not always set in a more virtuosic style than the fully-scored sections as might be expected if they were intended for soloists. Also, in Leonel's music a correlation cannot be found between increased speed and those duets marked 'duo' or 'unus' in the manuscripts.[28]

MENSURAL EQUIVALENCE

To return now to the question of equivalence across changes in mensuration, Mendel noted the problem and called for a gathering and sorting of evidence from both theorists and the music itself.[29] Berger subsequently carried out the former task and concluded that most

---

[29] Arthur Mendel: 'Some Ambiguities of the Mensural System' in Studies in Music History: Essays for Oliver Strunk, ed. H. Powers (Princeton, 1968), pp.137-61.

contemporary theoreticians favoured breve equivalence.[30] This runs contrary to much modern opinion on the subject. It is noteworthy that editorial marks of breve equivalence have been deleted in the second, revised edition of Dunstable's works. As a first step towards answering Mendel's second call, Wegman included a comparison of note values in O and C as part of his tempo investigations. As his brief was to observe how practices changed with time, he performed the calculations on thirty-five English masses written by various composers covering a rather large time span, including only four works by Dunstable and Leonel. This present study is able to perform a more thorough investigation of the subject applied to the complete works of just these two composers.

The following discussion assumes that the average perceived speed of music did not change under different mensurations and that chord lengths give a realistic measure of this perceived speed. To illustrate the validity of these ideas a simple case will first be examined. Under the signatures O and ¢ a breve contains the same maximum number of minims - six. The chord length in both these mensurations should therefore be the same no matter whether the breve or minim is taken to be equivalent. Only three pieces in this corpus use both signatures,[31] but in each case the average chord lengths

---

[30] Anna Maria Busse Berger: op. cit.

[31] In one of the cases, Dunstable's Quam, the ¢ section is transcribed in augmentation by Bukofzer as indicated in the original manuscript by flagged semiminims. See MB8. Hamm supports the interpretation and notes that this

are, indeed, very similar.

It is unlikely that all duple metre music was intended to be slower than that in triple metre, yet the average chord length measured in terms of the minim is usually longer in C than in O. Minim equivalence would presumably give equal lengths on average; a proportion of 1:1. In breve equivalence, six minims in O would be sung in the time of four in C. We would therefore expect music in C to compensate for the reduction in speed by using shorter length note values. The exact proportion would be 1:0.66. This is, in fact, the reverse of what actually happens in this corpus.

A clue as to the correct interpretation may be held by two of Dunstable's compositions. His Salve regina (MB8 no.46) is transmitted in two Continental manuscripts and his Regina celi (MB8 no.38) in four. Both have their duple metre sections indicated ₵. In breve equivalence, this would indicate eight minims in duple time to be sung in the same time as six in triple time, giving an average chord length proportion of 1:1.33. The actual figure for Salve regina is 1:1.38. That for Regina celi is 1:1.37.

In this period, C in insular manuscripts is often substituted by the diminution ₵ in Continental concordances. Perhaps the Continentals were correcting a bad English habit of writing C when they really meant ₵.

---

mensural practice was an English trait. See Charles Hamm: 'A Chronology of the Works of Guillaume Dufay' (diss. University of Princeton, 1964. Published Princeton, 1964; reprinted New York, 1986), pp.53-54.

More musical examples suggest that this may have been the case. Dunstable's Gloria, MB8 no.2, which is contained only in an insular source and employs the C mensuration sign, has a proportion of 1:1.36. His Agnus, MB8 no.14, and the motet Gloria sanctorum (MB8 no.43) both have a proportion of 1:1.30. Fewer compositions by Leonel juxtapose these two signatures, but one of those which does, his Regina celi (CMM50i no.19), has a proportion of 1:1.29.

Some other compositions show less ideal proportions, but then some variation is to be expected. Maybe sections in different mensurations were sometimes designed to be performed at different speeds to provide an element of contrast. Also, some pieces were indeed intended to have minim equivalence. Dunstable's Credo, MB8 no.16, has almost identical rates for duple and triple metre and its Gloria twin (MB8 no.15) has very similar rates. It is very interesting that both these pieces introduce the change to C mensuration at slightly different positions in the three voices so that the complete transition takes place over a few bars. This makes it imperative that the minim value remain constant. It is possible that Dunstable introduced this transition as a means of deliberately achieving an effect that was in opposition to the usual interpretation of the day. The Gloria and Credo on Alma redemptoris attributed to Leonel (CMM50ii no.18) similarly have nearly the same rates for duple and triple sections. A transitional dual time signature is used in the anonymous Sanctus and Agnus which probably form a

cycle with these movements.

Hamm and others explain the time relationships differently. In CMM50i (p.XX), he describes two types of duple time. The first has movement in semibreves and minims under the sign C with a beat on the semibreve moving at the same speed as that in O, thereby implying semibreve equivalence. This is actually the same as minim equivalence as in both these mensurations two minims equal a semibreve. It corresponds to the case in Dunstable's mass pair discussed above.

His second type moves in breves and semibreves and is marked C or ₵. In other words, he acknowledges a shorter average note length and also the fact that the two duple time signatures can be used in the same context. However, he maintains semibreve equivalence and states that ₵ is not a duple proportion, but rather an indication of a different, faster tempo (but not twice as fast). He gives ♩=70-80 for O and ♩=100-120 for ₵. Hamm has therefore arrived by a different route at a speed differential very similar to the 1:1.33 derived in this present study.

MENSURAL SCHEMES

It is convenient at this point to mention the differences in usage of mensuration signs between the composers Leonel and Dunstable. Some mensural schemes seem to be characteristic of English compositions in general and have often been used as a factor in the identification of such

pieces in continental manuscripts. Their value in differentiating one English composer from another is more limited. Compared with his contemporaries, Dunstable appears to use a wider variety of signs and proportions, although it is difficult to assess the interference of continental scribes in this respect. Leonel is noted for his rhythmic complexity, achieved by the use of different mensurations simultaneously, though this is confined to a few mass movements (CMM50ii nos.13-16) and is not a constant feature of his style. In these pieces voice I is written in doubled values throughout to facilitate the notation of small time values. Further rhythmic complexity in the form of cross-rhythms is often indicated by passages in coloration. None of the pieces with conflicting attribution to Dunstable resembles this style category.

RELATIVE VOICE SPEEDS

Another feature connected to note values is the relative speed of voices within a composition. Table 13 shows the speeds of the lower voices as a proportion of the speed of voice I. The figures are based only on fully-voiced sections of music to avoid any distortion caused by different rates of movement in duet sections.

The descant pieces of Leonel, at one extreme, have active lower parts. It is the norm in this style for voice II to be a cantus firmus and to be slightly less

active than voice III. At the other extreme, Dunstable's isorhythmic music with its slow moving tenor exhibits much more contrast between the voices. Not taking these two classes of pieces into account, a difference remains between the two composers, albeit in smaller degree. This is still most marked in voice III. There is co iderable overlap but 67% of Leonel's works give a figure of 0.62 or over, whilst 68% of Dunstable's give less than this value. It is also worthy of note that Leonel's mass music tends to have less mc ement in the lower voices than his motets.

The value of this test is not great as an accurate guide to authorship, but it is easily performed and could add weight to the results of other investigations. Other, more helpful, uses for the information could be in the comparison of possibly related movements of the mass, serving as a measure of similarity between them, or in the assessment of different manuscript versions of the same piece.

Excluding descant compositions, the voices in three-part music are always arranged in the manuscripts in the correct order as regards rate of movement, the most active being at the top of the texture and so on. This seems to have been a more important factor than voice range, which is sometimes at odds with the arrangement (see pp.51-53).

CHORD ANALYSIS

DISSONANCE LEVEL

Several years ago, Gareth Curtis used the concept of dissonance level in an attempt to distinguish between different fifteenth-century musical styles.[32] He found that the level varied considerably between pieces, even within the same style category. Even so, it was decided that a similar approach might reveal insights into the music of Dunstable and Leonel.

Curtis did not describe exactly how his figures were obtained and this study has not duplicated them exactly, probably due to a different method of calculation. However, roughly similar figures have been obtained for the few items common to both studies. As an extension to this present study, each piece has also been analysed for levels of perfect consonance and imperfect consonance.

A perfect consonance is here taken to be one involving only perfect intervals from the bass: those of a unison, fifth, octave and their compounds. Although the interval of a fourth is classed as perfect, chords involving a fourth (or eleventh) from the bass are normally prohibited in the music of this period and appear only in the context of dissonances; they do not often appear on the beat and are not used as resting sonorities,

---

[32] Gareth Curtis: 'Stylistic Layers in the English Mass Repertory ca.1400-1450' in PRMA, vol.109 (1982-3), pp.28-29.

for example at cadences. They have therefore been included here as dissonances.

All chords including at least one imperfect interval of a third or sixth (or their compounds) between any two voices, sometimes also in combination with perfect intervals, are treated as imperfect consonances.

In addition to those with a fourth from the bass, dissonant chords also include those which involve a dissonant second or seventh between any pair of notes. There is little evidence in this corpus for a successive composition of voices which, in the fourteenth century, would have allowed any interval between the other voices so long as they were each consonant with the tenor.[33] Chords such as a 6/5 are therefore treated here as dissonances.

The number of chords in each of the above three groups has been calculated and expressed as a percentage of the total number of chords for each composition. However, this produces rather biased figures as dissonances tend to occur only as short time values and perfect consonances as long ones. Durations for each chord-type are therefore also given in terms of a quaver length in modern transcription. Opinions vary as to the relationship of quaver lengths at a change of mensuration (see pp.69-73). However, any allowance for changes in speed should not significantly alter the proportion of

---

[33] For a recent opinion on the subject see Bonnie J. Blackburn: 'On Compositional Process in the Fifteenth Century' in JAMS, vol.40 (1987), pp.210-284.

chord-types. Unless otherwise stated, the percentages quoted in this discussion concern duration. Appendix 2 gives data relating to this chapter for the central body of three-part non-descant non-isorhythmic compositions.

The rate of dissonance of three-voice chords can be compared with that for the whole piece and, where appropriate, to that for four-part chords. In general, as might be expected, the more voices that are included, the more clashes occur and the more dissonant the harmony becomes. Leonel's Gloria CMMii no.8, the only piece in the database to include five-part writing, illustrates this principle. The rise in dissonance is accompanied by a rise in imperfect consonance and a decrease in perfect consonance. Rounded-up percentages are as follows:

No. parts	two	three	four	five
Dissonance	9	15	20	28
Imperfect consonance	41	50	69	72
Perfect consonance	51	35	11	0

The figures obtained for all pieces by each composer have been combined to show the spread of results, mean and median results and standard deviation from the mean for different types of pieces (see tables 14-15). The variation amongst pieces by the same composer is surprising. Dunstable's Quam pulchra (MB8 no.44) has often been noted for its consonant style and it is no surprise that this composition shows a low level of dissonance (4.48%). At the other extreme, his Kyrie MB8 no.1 shows the highest level at 19.33%. This last figure might in part be due to errors in transmission as the only surviving manuscript source is unclear in many details.

Neither of these pieces is representative of Dunstable's style. Leonel shows an even greater spread of results, as demonstrated by the larger standard deviation. This is mainly due to his descant pieces which are generally low in dissonance. The highest occurrence is in his Credo CMM50ii no.11 which has an overall level of 16.56%.

Comparing the average results for Dunstable with those for Leonel was disappointing from the point of view of differentiating composer style. Not only is the spread of results large, but the mean values are very similar. It has often been assumed that the 'sweet' style of Dunstable's writing, as admired by Continental musicians and often commented upon, is due to its consonant nature. It is worthy of note that Leonel, maybe a generation ahead of Dunstable, was producing music with a very similar pattern of consonance.

A more characteristic and narrower spread of results was obtained for groups of pieces in specific categories, for example descant or isorhythm. These results are interesting and worthy of more detailed comment.

It might have been expected that the dissonance level in Dunstable's isorhythmic pieces would be higher than the norm due to the immutable nature of the tenor and the slightly antiquated form of composition. However, the mean dissonance level is almost identical to that of his other works. The spread of results and therefore the standard deviation is smaller, however, indicating a consistency of style amongst these pieces.

The group I pieces by Leonel have, as might be

expected, a lower dissonance level than his later pieces but still a higher level than might have been expected from general conceptions of this style. The level of imperfect consonance is also lower and the level of perfect consonance higher.

The most valid comparison between the composers concerns those pieces which fall outside these two groups. Here there is a small difference in consonance levels, but insufficient to help in the determination of authorship due to the wide spread of results. Levels do prove to be of help in Part Two, however, in the comparison and evaluation of related mass movements whose patterns of consonance and dissonance sometimes prove to be very similar.

A more marked difference exists with respect to four-part writing in which Dunstable uses a much higher percentage of perfect consonance than does Leonel (22.59% of four-note chords compared with 14.63%). Even the three-part chords within this texture show a similar difference (31.27% compared with 21.38%). This cannot be accounted for simply by the difference in composition types as isorhythmic and non-isorhythmic music in three parts does not show a comparable difference.

Various other types of chord level in three-part music were calculated to try to isolate composer-specificity, with little success. For instance, there was little difference in the use of second inversion triads. The levels of full triads employed are included in the tables to demonstrate the variation between the

different types of composition, although Dunstable's non-isorhythmic and Leonel's non-descant works again show a very close correspondence.

Fuller has recently described two types of imperfect chord.[34] The first contains only one imperfect interval combined with one perfect, for example a fifth and a third (5/3). The other contains two imperfect intervals, for example a sixth and a third (6/3). This latter type she calls doubly-imperfect and suggests that it should be set apart from other sonority types. Chords of the type containing a repeated imperfect interval (i.e. the upper parts in unison) are not discussed, so it is not known how Fuller would classify these. In any event, no great difference can be found between the levels of different types of imperfect chord in Dunstable and Leonel's three-part music.

Although four-part music does not enter into Fuller's study, it follows that three classes of imperfect chord would exist in this case: singly, doubly and triply imperfect. Assuming that repeated intervals are allowed, the mean percentage levels of four-part chords for Dunstable and Leonel are as follows:

	singly	doubly	triply
Dunstable	46.09	14.29	3.24
Leonel	42.10	20.51	6.55

Dunstable seems to favour singly imperfect and Leonel doubly imperfect chords. The proportions of these two

---

[34] Sarah Fuller: 'On Sonority in Fourteenth-century Polyphony: Some Preliminary Reflections' in Journal of Music Theory, vol.30.1 (1986), p.42.

chord-types are respectively three to one and two to one for the two composers.

Another relationship which has been investigated is that between perfect and imperfect consonance. During the fifteenth century there was a gradual shift away from bare perfect consonances and towards a universal use of full triads, even as final chords. In theory it should be possible to map this transition by comparing the levels of these chords as used by various composers. It was decided to do this for Leonel and Dunstable. The ratio of perfect to imperfect three-part chords was calculated for each piece. The results are given in Table 16.

The picture which emerged was very surprising. There seems to be no consistency for either composer. The ratio, which decreases as music becomes more triadic, varies from 0.68 to 0.25 for the non-descant compositions, with a mean of 0.48 for both composers. Only when the descant pieces of Leonel are considered in isolation is a difference detected. The mean for these pieces is 0.63, showing them to be in general more harmonically primitive, in keeping with the theory that they are amongst his earliest works. The range of values is again wide; the most exceptional is that for Beata progenies, CMM50i no.1, with a ratio of only 0.29.

As a logical progression, it might be that increasingly larger proportions of imperfect consonance reflect the subsequent chronology of composition of the non-descant pieces. Hamm, in the collected edition, has attemped to arrange Leonel's pieces chronologically

according to style. A statistical correlation calculation performed to compare his ordering of these pieces with the ratio of perfect to imperfect consonance present in each one does demonstrate some association between the two, though not strongly. For the motets the coefficient of correlation is 0.341 and for the mass movements 0.396. The latter value only is significant at the 0.05 confidence level. No chronology is available for Dunstable's works, though Howlett has suggested a date of 1426 for Dunstable's motet Albanus roseo (MB8 no.23).[33] This would place it reasonably early in his career, though the piece does not have a high ratio (0.45).

ACCENTED DISSONANCE

In works of dubious authorship, the type of dissonance employed has often been cited as reason for favouring one composer over the other, though usually without further explanation. For example, Bukofzer considered that the 'treatment of dissonance' in Salve mater salvatoris (MB8 no.62) suggested Leonel as the author (MB8 commentary). Emphasis is usually placed on Dunstable's 'pan-consonant' style and his care in approaching dissonances,[34] so there seems to be an implication that the dissonances employed

[33] D.R. Howlett: 'A Possible Date for a Dunstable Motet' in MR, vol.36 (1975), pp.81-84.

[34] See, for example, Margaret Bent 'Dunstable, John' in Grove, vol.5 (1980), p.723.

by Leonel are somehow cruder or less well prepared.

Reid has very successfully used dissonance treatment to differentiate the style of Dufay from that of other composers.[37] His study appears to have been in great depth, classifying every dissonant occurrence in terms of type, duration and resolution. It would, in theory, be possible to apply his methods to the music of Leonel and Dunstable, though the enormity of the task made it impractical as part of this present study (Reid's whole PhD thesis was confined to that single subject). There is also some doubt as to whether such a project would be so successful for this corpus. Dufay is noted for his systematic use of dissonance which sets him apart from other composers of his generation, so it is not surprising that this element of his writing alone can serve as an indicator of his style. The use of dissonance in the English school is, by comparison, cruder, more variable and less easy to classify. Also, the generally low level of dissonance, which has been noted as a characteristic of insular music in general, means that there would be less material on which to conduct a statistical analysis. This present approach, in which dissonance is considered in less detail but alongside other features of style, is probably more suited to the music.

Most of the dissonance present in this corpus is unaccented, produced by the natural movement of upper voices over a slower tenor. It was decided that, in a

---

[37] John W. Reid: 'Testing for Authenticity in the Works of Dufay' in MR, vol.45 (1984), pp.163-178.

compromise to Reid's study, an investigation of the smaller proportion of accented dissonance would probably provide the most interesting data on differences between Leonel and Dunstable. A computer programme was designed to locate all dissonant combinations occurring when new chords are struck. Once found, these were easily classified 'by hand' into various types. It is possible that the methods used overlooked a small amount of what would normally be classed as accented dissonance, for example where a suspension consists of a tied note so that no completely new chord combination is struck on the beat. However, the same approach was used consistently throughout the corpus.

The overall level of accented dissonance does vary between the two composers, Leonel showing a slightly higher level than Dunstable. As the level of dissonance has been shown to vary depending on the number of voices involved (see above p.79), it was not thought valid to compare overall levels in pieces containing different proportions of duet writing. Separate calculations were therefore performed for two- and three-part chords. To eliminate any correlation with varying relative voice rates between the composers (see pp.74-76), the percentages are out of the level of accented chords, not of the total chords in a composition. The calculations involving duration of dissonance produced a slightly greater separation between the composers than those involving numbers of chords. For the results see Tables 17-18. Pieces with no true duet writing are excluded from

LEO	2.34	2.32

In contrast to the levels of dissonance overall, those for accented dissonance are quite similar for two- and three-part music, remarkably so for Leonel. The slight difference in this respect between the two composers prompted a comparison of two- and three-part levels for each individual piece but the results were not consistent enough to use as a test for authorship.

Levels of dissonance must be treated with caution. It is possible that some may be the result of manuscript errors; the majority could be avoided by the alteration of a single note. Where the same pieces have been found in two different sources there are usually slight discrepancies between them. Where more than two sources exist, a majority verdict can be passed on the correct interpretation of varying passages, although where insufficient information is available, the possibility must always exist that some of the transmitted dissonance was not originally intended. Conversely, it is very tempting in transcribing manuscripts to eliminate dissonance by altering the source material in the assumption that mistakes have been made by the scribe. Because of this, some intended dissonance may not be evident in modern trancriptions. As has already been stated, the encoding of music for this thesis has been performed mostly from the versions in three collected

editions and it is possible that editorial policy has varied between them. This slight uncertainty cannot be avoided unless the original manuscripts are consulted in every case. However, as far as scribal error is concerned, it is equally likely to occur in the works of both composers, so the higher level in the works of Leonel probably reflects a real difference between the two. It would be unwise to use levels of accented dissonance as a sole indicator of authorship, but they are useful in combination with other tests and so long as the condition of the original manuscript is taken into account.

The dissonant chord types will now be examined in more detail. The level of accented dissonance overall is quite low, so most chord types occur only once or a few times in the works of each composer - too rarely to make sense in statistical calculations. In comparison, a 7/3 chord occurs quite often, but in roughly equal numbers in both composers (24% of all cases of accented dissonance in Leonel and 21% in Dunstable). The bare fourth in two-part writing, however, is almost as frequent and more than twice as common in Leonel (62% of cases of two-part accented dissonance as opposed to 30% in Dunstable). Added to the fact that accented dissonance is more common overall in Leonel, the presence of three or more bare fourths in a single piece is an indication of composition by him, although most works have insufficient two-part writing to make this method of identification possible in more than a few cases. It may be more valuable in considering whole mass cycles where a larger sample of

music is available.

An examination of the function of the accented dissonance also reveals small differences between the composers. In both it is employed in the approach to cadence points and in similar amounts, though in Leonel much more is not associated with cadence points (59% as opposed to 38% in Dunstable). Surprisingly, the music of both contains similar numbers of non-functional occurrences which cannot be explained in terms of any sort of unessential note or cadence approach. This is evidence to support the theory that some of this haphazard dissonance might be due to manuscript error. If these instances are not taken into consideration, the level in Dunstable not associated with cadence points falls to 19% and almost all of this consists of accented passing notes.

The actual types of dissonance counted are shown in Table 19. While Dunstable uses appoggiaturas only at the approach to a cadence, in Leonel they occur in other positions, and occasionally even at what might otherwise have been a cadence point (see Example 1). Leonel favours ascending, and Dunstable descending auxiliary notes.

Example 1. Leonel Credo 13

CHORD TYPES

As an examination of dissonance levels alone did not provide enough information to distinguish effectively between the music of Dunstable and that of Leonel, it was decided that a more detailed study would be undertaken, analysing each piece for individual chord types. The results are extensive and difficult to abbreviate so the appendix gives them in full but only for the central body of three-part works.

Four-part pieces were particularly difficult to analyse. The limited memory capacity of the BBC computer meant that the large number of different chord permutations possible with this number of parts could not be handled simultaneously. The problem was finally solved by dividing the task into seventeen different programmes to run in succession.

A preliminary step in every analysis was the dividing of each piece into two, three and, if appropriate, four-part voice combinations. The descant pieces of Leonel consist almost completely of three-part harmony; there are very few rests in the texture. The more common style, however, involves frequent resting of voices and duet interludes. On average, a three-part Dunstable composition is only 60% three-part chords, although this figure varies considerably, depending on the length of the duet sections. Four-part pieces contain even more rests so that the texture does not become dense. They consist, on average, of 45% four-part and 30% three-part chords in

Dunstable. Leonel employs a slightly higher proportion of four-part chords.

In order to analyse each chord it was necessary to order the notes as regards pitch. This being the case, the computer programme was also designed to keep note of the number of chords involving crossing of the voice-parts. This number was very variable, reflecting, in part, the distance apart of the voice ranges, a subject dealt with elsewhere. Leonel's descant pieces, however, contain very little crossing - a feature characteristic of this style.

In the tables, chords are described by specifying exact distances from the lowest note. 6/3 indicates a three-note chord with notes a third and sixth above the bass. It does not indicate any other arrangement of a first inversion chord.

Some small differences in chord frequency as used by Dunstable and Leonel are apparent. For instance, it was noticed that in four-part compositions, the average levels of certain chords showed differences of several fold. The wide variation in level from piece to piece renders most of these chords unreliable indicators, although two particular ones give consistently characteristic results. Their mean levels are:

	Leonel	Dunstable
6/5/3	1.07%	0.11%
7/5/3	1.94%	0.56%

This finding, though possibly an indicator of authorship, must be treated with caution. It may be that the smallness of the sample of four-part pieces accounts

for the inequality of the results between the two composers. Also, the sets are dissimilar in that four out of five of the Dunstable but none of the Leonel pieces are isorhythmic.

The results for the three-part pieces, for which there is a more satisfactory sample size, contain no such immediately obvious indicators. The figures show a wide variation from piece to piece. At first sight, little can be done to distinguish the composers. However, several weeks of determined effort and manipulation of figures produced the following successful method.

First, to show overall average levels of chord usage by the two composers, analyses were produced combining all the ascribed non-descant, non-isorhythmic pieces for each one. From these it was possible to compare in detail the levels of particular chords. For a particular chord type, the mid-point was then taken between the levels for Dunstable and Leonel. The level for each individual piece can therefore be compared with this midpoint to determine on which side it lies. Although no single chord-type gives useful results, if the levels for every chord-type are treated in this way and the scores combined, a more meaningful picture appears.

Simply adding together the differences for every chord produced results which reflected mainly the levels of those chords which appear in high numbers. For example, differences of a few percent in levels of 6/3 chords swamped differences of a small fraction of a percent in chords of lower frequency. A scheme was

therefore developed which calculates the difference of the chord level from the average in terms of a multiple of the average, for example if an average level is 2% and the level in the piece in question is 4% the piece will score two in favour of one composer.

All the scores are combined, the scores in favour of Dunstable being subtracted from those in favour of Leonel. The resulting figures are adjusted to make the average zero. A composition by Dunstable is therefore indicated by a negative figure and one by Leonel as a positive figure. These 'chord differences' are shown in Table 20.

Of all the tests developed in this project, this one achieves the most successful separation of Leonel and Dunstable. Very little overlap exists between the values for the two composers. Leonel's Gloria, CMM50ii no.10, is transitional in style between descant and his more advanced pieces. Nevertheless, a low score should be regarded as inconclusive. The very high score in favour of Dunstable for Ave maris (MB8 no.35) might be due to the shortness of this composition providing only a small sample of chords.

MELODIC STRUCTURE

This chapter of the investigation concerns the intervallic structure of melodies, each voice-part of a composition having been subjected to a separate analysis. Successive notes in the melody were compared and the interval between them computed. Intervals with an intervening small rest marking a phrase end were included, but not those where the rest is sufficiently long to render the melody severely disjointed, as when the other involved parts perform a duet.

The computer programme performing the analysis was designed to classify intervals as species of major, minor etc. The prepared melody files take into account all sharps and flats transmitted by the sources, including both key signatures and accidentals added in the course of the piece, as discussed on p.30, though in performance these pitches would probably have been modified according to the traditions of musica recta and musica ficta. Despite much modern discussion of these processes, there is still no complete understanding of contemporary practice, so it is impossible to perform an analysis which takes it into account. For this reason, the figures obtained could be slightly inaccurate and so most of the observations to be made are based on the collective figures for each interval type, for example all thirds irrespective of species. The results, abbreviated in this way, are listed in Appendix 3.

The use of plainsong in some compositions might be

expected to govern the melodic structure. In fact, where a chant is employed in paraphrase in an upper voice, the results are indistinguishable from those of freely-composed melodies. The borrowed melody in these cases is often decorated to such an extent that the result must reflect the composer's personal style. It is quite possible that amongst those melodies thought to have been freely-composed some may have been based on an as yet unidentified chant. It has therefore not been considered necessary to treat any of these voices differently.

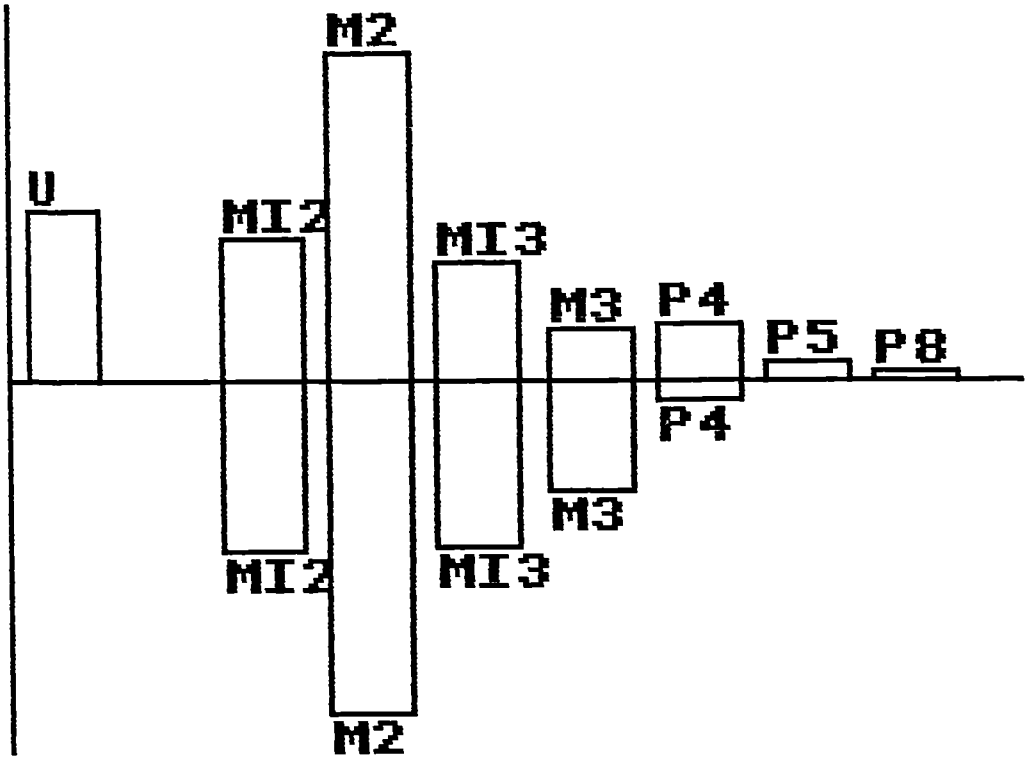
Where the chant is used undecorated in the tenor, as in the isorhythmic technique, the intervallic structure is not representative of the composer's style (except in as much as that he had free choice of the portion of chant to be employed). Also, in pieces with a slow-moving tenor, the number of notes appearing is often not sufficient on which to perform a meaningful statistical analysis and the results are anomalous. The lowest voice is therefore not a good indicator of personal compositional technique in this corpus (though Morehen has used it as a basis for defining Byrd's style).[30]

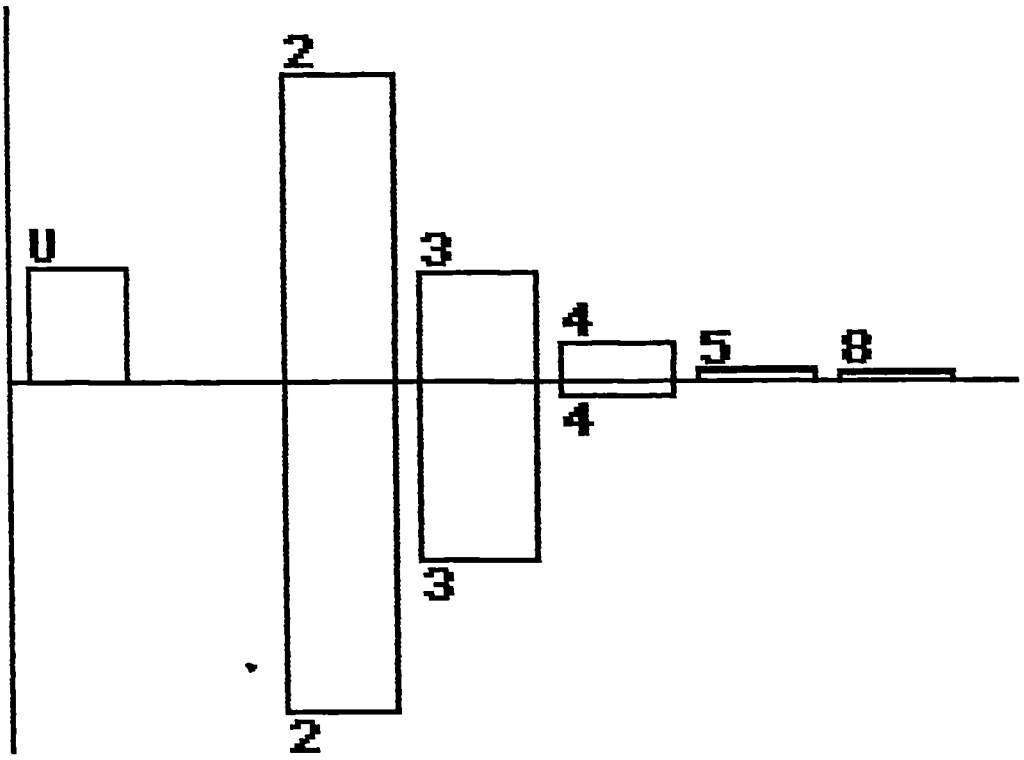
The structure of a typical voice is easily visualized in the form of a graph. Figure 6 is that for voice I of Leonel's motet Anima mea (CMM50i no.18). Ascending intervals are indicated above the x-axis and descending intervals below. That melodic movement is largely

---

[30] John Morehen: 'Byrd's Manuscript Motets: a New Perspective' in Byrd Studies, Ed. Alan Brown and Richard Turbet, (Cambridge, 1992), pp.51-62.

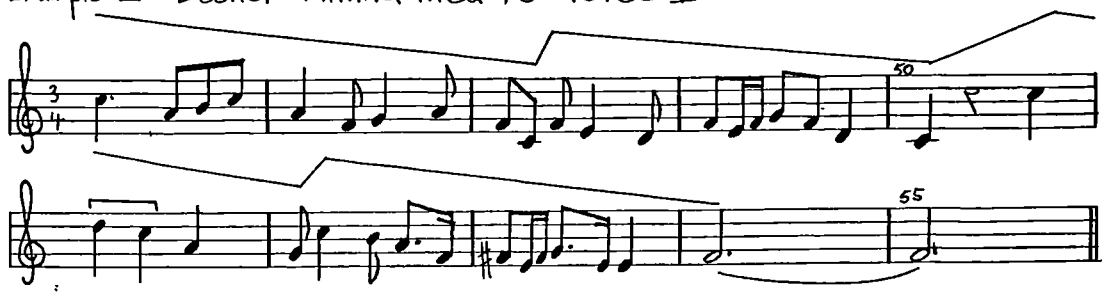
Figure 6 Melodic intervals in Leonel's Anima 18 voice I





stepwise is obvious from any brief survey of the music in score. In this motet over 62% of intervals are a second. The overall average for the upper voices in Dunstable is 56% and in Leonel 60%. Large intervals tend to be ascending ones and consequently the stepwise movement has a downward bias. The melodic contour thus often takes on a 'sawtooth' appearance, phrases beginning by upward leap and continuing by descending steps. This is illustrated in E ample 2. In this voice, the mean interval sizes for ascending and descending movement are 2.55 and 2.40 steps respectively. The ratio of descending to ascending movement is 1.11 - a typical value.

Example 2 Leonel Anima mea 18 Voice I



In general, the larger the interval, the less commonly it occurs. It is usual to find an occasional ascending octave, but other intervals of over a fifth are quite rare, occurring only once in every three hundred notes (0.36 percent of intervals). Table 21 shows the mean rates of occurrence for these rare interval types in three-part compositions by Dunstable and Leonel. Descant and isorhythmic pieces are excluded.

There are many more large intervals in voice II than in voice I. Many indications are present in the music of

this period that the method of successive composition in which each voice was written in turn against the tenor was giving way to a more harmonic viewpoint in which all the parts had to be considered in combination.[39] The use of larger, less melodic intervals in voice II indicates that the smoothness of this part was considered to be less important than that of voice I and also less important than its function as a harmonic 'filler'. The early pieces of Leonel exhibit a much smoother line in voice II than do his later works, reflecting this change in emphasis.

Dunstable, on average, uses more ascending octaves than does Leonel, especially in the lower voices, but the levels in individual compositions are too low to be a reliable indicator of authorship. However, the overall use of large intervals in the upper voices combined is a little greater in Leonel than in Dunstable (average levels 0.43% and 0.31% respectively). The distribution is shown in Table 22.

Sometimes, especially in Dunstable, large intervals seem to have a thematic function, appearing more than once in the same context and/or at the same pitch within a single piece. This is most obvious in the isorhythmic motets where repeats of a tenor color are often harmonized in a similar way. For example, in Albanus roseo (MB8 no.23) an ascending seventh from G to f occurs seven times in voice II. Whilst amplifying the effect, the reharmonizations are not solely responsible for the

multiple appearances of this progression, which is present against all three tenor colors. The phenomenon is also found in non-isorhythmic compositions such as Salve Regina (MB8 no.46) which has seven instances of a rising seventh C-b in different contexts. The thematic link can extend to paired mass movements, serving to strengthen the unification between them and therefore the claim to common authorship. Dunstable's Gloria and Credo on Jesu Christe Fili Dei (MB8 nos.15-16) each have two instances of a rising seventh from C to b in voice II. Though both are composed over an identical tenor, the progression is, surprisingly, not associated with reharmonization in this case. Repeated large intervals are just the most obvious aspect of a more widespread use of melodic repetition and variation, a subject which deserves more detailed study.

Often, the large intervals are found between the last note of one section of music and the first note of the next, especially in voice III. It is debatable whether these should be regarded as part of the melodic line. Many others have an intervening rest marking the end of a melodic phrase. Most of those occurring in voice I are of this type, outnumbering those occurring mid-phrase by more than four to one. In voice III the picture is reversed. Voice II has more than twice as many mid-phrase large intervals as those between phrases, again showing that a smooth melodic line is less important here than in the top voice.

Table 21 confirms that, as discussed above, descending large intervals are much less numerous than

ascending ones. This comparison extends to fourths and fifths. Descending seconds and thirds are, however, more numerous than ascending ones. This reflects the general tendency towards descending phrases separated by upward leaps. To measure this tendency, the mean ascending and descending interval size has been calculated for each voice and compared. The ratio of these sizes averages 1.07 for both voice I and voice II and is the same for both composers, so cannot be used to differentiate between them.

The number of unisons present reflects the amount of declamation in the melody. In voice I Dunstable occasionally uses quite a high level, for example in his Credo MB8 no.5. Music with 20% or more unisons in this voice is more likely to be by him than by Leonel.

In voice I the only specific interval type which varies sufficiently between the two composers to allow differentiation of their styles is that of an ascending fifth. The levels of this interval in the ascribed pieces are given in Table 23. The mid-point between the averages for Dunstable and Leonel is 0.705%. A higher result than this favours Leonel as composer, a lower result favours Dunstable. In this way, 74% of cases correctly predict the author. However, it is noteworthy that there is a small concentration of Dunstable's compositions giving a high result. This produces a polarization of figures for his music.

The structure of voice I is seen to be very similar in all other respects for both composers. Consideration

of the other interval types does not increase the separation of values. For voice II, however, more overall differentiation is possible. Hughes recognized the idiosyncrasy of this voice when he suggested that it might be possible to date compositions by the style of the contratenor.[40] The differences which can be shown to exist between Leonel and Dunstable in this respect are probably due to the changing nature of this voice. Though the data have been analysed in many different ways, a similar manipulation to that used in calculating chord differences (see pp.98-99) produced the greatest separation of results.

The calculation of interval differences excludes intervals of a sixth and over as these have already been considered in the previous paragraphs and duplication of information would produce a bias in the testing. Ascending and descending intervals of a second, third, fourth and fifth are included. For each piece, the levels are compared with the difference of the averages for each composer. A positive result indicates composition in the style of Leonel and a negative result in the style of Dunstable. This collective interval method is possibly more reliable as an indicator of authorship than that using only a single interval type.

Separation of the two composers is quite successful, though less so than that obtained with chord differences. This is probably because fewer interval classes than chord

types are involved, leading to the figures produced being quite small in value. However, authorship is correctly identified in 82% of the attributed works (see Table 24).

The sequence of intervals in a melody is a topic which deserves study. Certain melodic structures have been recognized as being characteristic of the English school during this period. One is a rising triadic opening. From the tables of interval frequencies it can be calculated that a rising third appears, on average, about once in every ten intervals. Its incidence at the beginning of a composition is higher than this, though the values for Leonel and Dunstable are similar at about one in three. The probability of two consecutive rising thirds would, by chance, be one in a hundred, yet three of our central Dunstable compositions begin in this way. Many more follow the rough outline of a triad, though here the calculation of probabilities becomes difficult; how many intervening notes are allowable before the pattern ceases to be triadic? This highlights the main problem in a statistical analysis of melody. Patterns which would appear similar to the eye would be discounted by a computer if a single intervening note varied.

Another common phrase beginning is a falling third. 23% of pieces open in this way, again a higher proportion than would happen by chance. In Dunstable this is usually followed by a further downward step of a second; the pattern in Leonel is more variable. This could be a factor in differentiating their styles, although as some melodies are based on chant its value is uncertain.

The so-called 'English figure', a melodic pattern associated with cadences, has often been discussed.[41] The most basic form, as in Example 3, is associated with coloration, though many variations on the figure appear. Again, the progression is a characteristic of English compositions in general and was employed by both Dunstable and Leonel, though a little more frequently by the former. During an investigation of cadence types (see p.123) its presence was noted in around 78% of Dunstable's and 59% of Leonel's pieces. Alone, it cannot serve as a marker of their individual styles but is potentially useful in evaluating compositions with conflicting ascription to continental composers.

Example 3 Dunstable Salve 46

TEXT

A study of the treatment of text does not produce a great deal which is useful to differentiate the music of Dunstable and Leonel. Their choice of texts seems to have been rather limited; all the motets are sacred in nature, none being on a political theme as is sometimes the case in Dufay. A noticeable emphasis on Marian subjects reflects the contemporary cult of the Virgin but otherwise the selection of subject matter is unremarkable and nothing obviously divides the two composers.

That textual considerations were of little importance in this period is verified by the inconsistency of underlay; it is often very vague with different manuscripts being at variance in their positioning of the words. Bukofzer, in his edition of Dunstable's works, often modified the underlay to correspond with that of the borrowed plainsong or to take into consideration matching motifs between voices. There is no evidence to suggest that fifteenth-century musicians would have taken pains to be so accurate. No doubt the underlay is more often a reflection of scribal practice rather than composer intention. It is, therefore, questionable whether its study would reveal any useful information.

A further disregard for clear articulation is demonstrated in the polytextual nature of the isorhythmic motets. A similar effect is achieved in settings of the Credo which telescope the text in order to limit the length of the movement. This was a characteristic feature

of English mass settings in general and was used by both Dunstable and Leonel, although Dunstable also uses the technique in two Glorias.

Obvious correlations between text and style are lacking, the overall mood of the music rarely reflecting that of the changing subject-matter. The difficulties of ascertaining the correct underlay (compounded by the well-intended interference of modern editors) make word-painting impossible to assess in transcription. In one example where the present writer has had cause to study the original manuscript,[44] the word 'morte' appears to be associated with an accented appoggiatura. It could also have been intentional that Dunstable's Credo on Jesu Christe Fili Dei (MB8 no.16) sets the words 'descendit' (bb.68-70) and 'ascendit' (bb.96-97) to falling and rising figures respectively, but in other places similar associations seem to be absent, even in the most likely situations. A cursory appraisal of the music of Dunstable and Leonel does not reveal any difference between them in this respect, so further investigation was deemed unwarranted, especially as word-painting, if it did exist, would be very difficult to quantify.

One characteristic which can easily be measured, however, is the density of text within a composition or, in other words, the amount of music set to a given length of text. Texting of the lower voices is erratic; sometimes they are given text, sometimes just an incipit

---

[44] The Kyrie Lux et origo, possibly by Leonel, b.59. A transcription is given in the appendix to Part Two.

and sometimes no indication at all. Also, they vary in nature, sometimes resembling the free-flowing top voice, and sometimes being so unvocal as to lead many past writers to hypothesize an instrumental execution. Due to these problems and uncertainties, and to ensure easy comparison of different pieces, the density of text in voice I only will be considered here. One composition by Dunstable (MB8 no.34) is untexted and so excluded from consideration.

The number of syllables given to the top voice in each composition has been counted. From this, the number of notes per syllable and also the number of minims per syllable can be calculated. An 'Amen' at the end of a piece is very often given a more extended melismatic treatment than the rest of the text. This produces a distorted figure for the general density of text. The 'Amen' portions have, therefore, been excluded from the calculations.

The results are shown in Table 25. As can be seen, the variety is too large to help indicate authorship in all individual cases, although a few conclusions can be m de. The number of minims per syllable gives larger results and a slightly greater separation between the two composers, so the figures quoted hereafter will concern this ratio. Dunstable on average spreads his text a little more thinly than Leonel. Fourteen or more minims per syllable points to composition by him. The mean results for each composer are shown below.

Table 25 Text Density in voice I

	Dunstable	Leonel
mass movements	7.02	5.45
motets	8.04	7.17
overall	7.57	6.22

Only when comparing pieces on the same text can an accurate comparison of the composers be made. This is possible using mass settings, especially those of the Gloria and Credo as enough of these are known to give a clear picture.

	LEO	Gloria 10	2.40			
	LEO	Gloria 16	2.99			
			3.11	DUN	Gloria 7	T
	LEO	Gloria 18	3.31			
			4.88	DUN	Gloria 15	
			5.13	DUN	Gloria 4	T
			5.40	DUN	Gloria 11	
			5.89	DUN	Gloria 9	
			6.62	DUN	Gloria 2	
T	LEO	Credo 19	1.54			
T	LEO	Credo 14	2.05			
			2.05	DUN	Credo 5	
			2.25	DUN	Credo 8	T
	LEO	Credo 13	2.29			
	LEO	Credo 11	2.61			
			3.02	DUN	Credo 16	
T	LEO	Credo 18	3.44			
			3.56	DUN	Credo 17	T

As can be seen, the separation for the Gloria movements is almost complete. A figure for a Gloria of less than three minims per syllable points to Leonel as composer. On the other hand, a figure of more than four points to Dunstable.

Settings of the other mass movements (Kyrie, Sanctus and Agnus) survive in too few numbers to make a reasonable comparison of the composers. Those which are available, as might have been expected from the short text, have a

large number of minims to the syllable. In comparison, the Gloria and Credo are very long texts and are set in the most compressed way. It might have been thought that where telescoping is employed in these movements, greater room would have been given for a more melismatic treatment. In reality, the telescoped movements (indicated 'T' above) are often the most syllabic.

CADENCES

Phrase lengths are generally short in the music of Dunstable and Leonel, so a large proportion of any composition consists of the preparation and execution of cadences. These progressions are therefore so important that no comprehensive study of the corpus can be complete without considering them, although to do so is problematic, mainly due to the difficulties of defining the term 'cadence' as it relates to this historical period. A quantitative analysis must attempt such a definition, although for several reasons the task is not as straightforward as might initially be thought. Many different cadential formulae occur in the music and it is sometimes difficult to say whether a cadence was intended at any particular point. Most textbooks can afford to select convenient isolated examples as illustrations of the norm (leading students to a necessarily simplified view of the music), but an analysis of a complete corpus cannot ignore unusual instances.

Wienpahl conducted a survey of cadences in order to trace their development through the course of the fifteenth century.[43] Although not expressly stated, he seems to have overcome the problem of defining cadence points by examining only the final cadence of each composition. This method has the advantage of consistency

---

[43] Robert W. Wienpahl: 'The Evolutionary Significance of 15th Century Cadential Formulae' in JMT, vol.4 (1960), pp.131-152.

but misses out on accuracy as the overall use of more advanced formulae is underestimated. It is perhaps natural for composers to have fallen back on well-worn progressions with which to conclude a piece, rather than new or experimental ones.

A cadence should occur at the end of a phrase. Sometimes a cadential formula occurs mid-phrase and a subjective judgement must be made as to whether the term 'cadence' is applicable in each case. Such subjectivity need not invalidate any conclusions of the investigation so long as the problem is acknowledged and an effort is made to keep judgements consistent throughout. However, it may be difficult for different workers to reproduce the same results, as a degree of personal interpretation is inevitable.

In contrast, phrases and even whole musical sections occasionally end with very strange progressions which do not resolve or sound even remotely cadential. This happens most often in isorhythmic pieces where the structure is dictated by form and not phrase; many phrase-endings cannot cadence properly because of the configuration of the tenor melody. Also, slow-moving harmonies over a static bass do not allow frequent cadence points (although often giving the illusion of modern perfect and imperfect cadences at places where the harmony does change but where no cadence is intended). However, the phenomenon is not restricted to isorhythmic works.

Due to the variability in cadential formulae and the other problems discussed above, the locating of cadence

points by computer was considered to be more complicated than the 'by hand' method and therefore not employed. It must be admitted that, in consequence, the results are open to possible error, though extensive checking has been carried out. In order that no information be overlooked, it was decided to record every progression that could be even remotely cadential and also every progression occurring at a phrase end, whether a standard cadential pattern or not. For each occurrence the following points were noted, together with any other interesting observations:

i) Number of parts involved;

ii) Type of progression;

iii) Finality of the cadence;

iv) Whether a rest follows in voice I;

v) The approach chords;

vi) The movement of parts after the cadence;

vii) The cadence pitch;

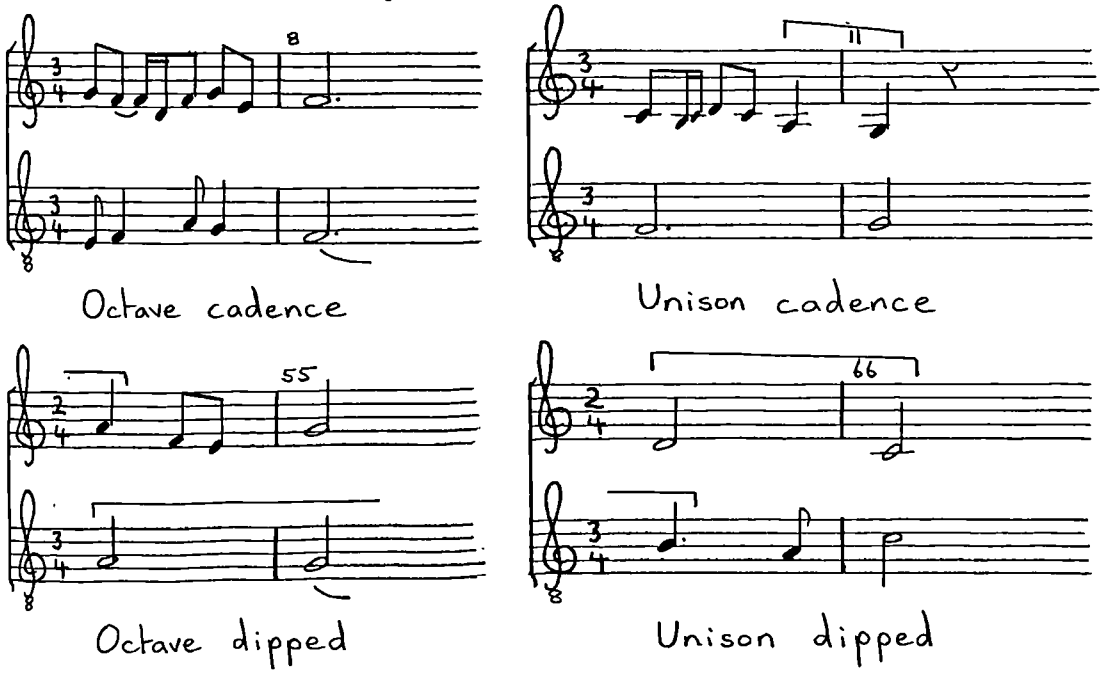
viii) The presence of the 'English figure'.

It was not considered appropriate to reproduce all this information here, mainly because of the amount of space it would cover. Also, none of it is obscure, and so can easily be observed from a score, unlike the computer-derived measurements of previous chapters. Some specific examples will be described in the following text, but mostly it will be sufficient to quote general rates of occurrence of the various progressions.

TWO-PART CADENCES

The description of the earliest cadence, an 'occursus' or coming together of parts whereby a unison or octave is approached by step in contrary motion, is still adequate to deal with most of the two-part writing of the fifteenth century. Often, the ascending voice dips a degree lower before resolving upwards, now by a third. This is most common in octave cadences, applying to the upper voice, although occasionally also occurs in the unison type, applying to the lower voice. For illustrations of all these types see Example 4.

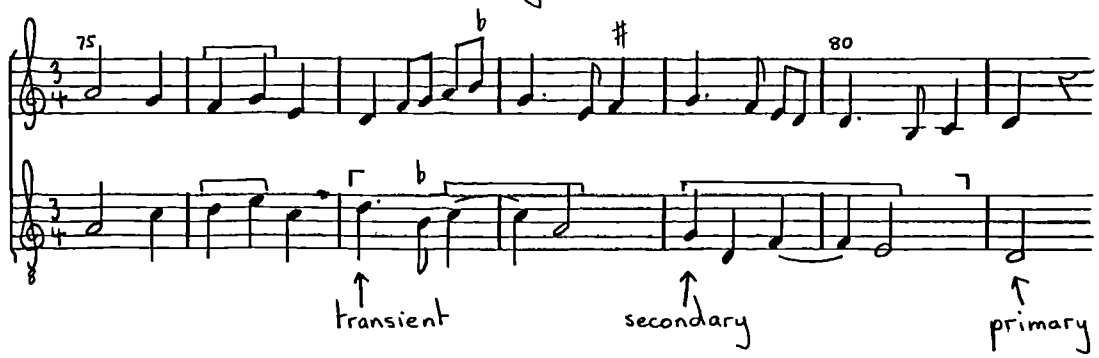
Example 4 Leonel Regina celi 19



Sometimes, where two and three-part phrases overlap, another voice enters at the cadence point, producing a three-part chord.

Not all unisons and octaves are necessarily cadences. Those approached by leap have been eliminated in an attempt to simplify the data collection, although an occasional phrase does end by leap, for instance by an upward fourth in the lower part. It was found useful to divide the remaining instances into three groups depending on the degree of finality of the progression (see Example 5). The first consists of main cadence points occurring at phrase ends, indicated by an ensuing rest or the end of a section of music. They resolve on long notes in relation to the general flow of the music. Secondary cadences are taken to be those occurring with no rest following but nevertheless with some pause in the flow of the music and/or a melodic preparation and increase of tension typical of a cadence. Tension is produced by an increased rate of flow of the parts and the presence of dissonance which is then resolved at the cadence point. The third category contains those transient progressions producing no halt in the musical flow and no melodic preparation. These are not considered to be true cadences and therefore not included in the following discussion.

Example 5 Dunstable Salve regina 45



A close inspection of the two-part writing of Dunstable and Leonel reveals no great differences in cadence type, although a few general trends are noticeable. Dunstable employs a slightly higher percentage of secondary cadences than Leonel (28% compared to 22%). Though the effect is difficult to quantify, his music also exhibits a clearer distinction between the two categories, the allocation of cadences to one or the other being more easily performed. The proportion of secondary cadences does vary considerably from piece to piece, and would only be of value in differentiating between the composers if a large sample of music was being considered, for example a whole mass.

Amazingly, the two composers gave the identical result of 18% unison cadences in the first category. However, Dunstable uses a larger proportion in the secondary type (40% compared to 27% for Leonel) which might in part explain the more distinct separation of categories.

Leonel in both categories and Dunstable in his second category have 26% of cadences with a dip in the ascending voice. However, a larger proportion, 33%, of Dunstable's main cadences exhibit this characteristic. If it is reasonable to suppose that the dip increases the tension of preparation, thus producing a firmer cadence, the larger proportion of this type of progression also adds to the distinction of primary and secondary cadences in this composer. A high proportion of 'dip' cadences in any one piece, though, does not necessarily indicate composition

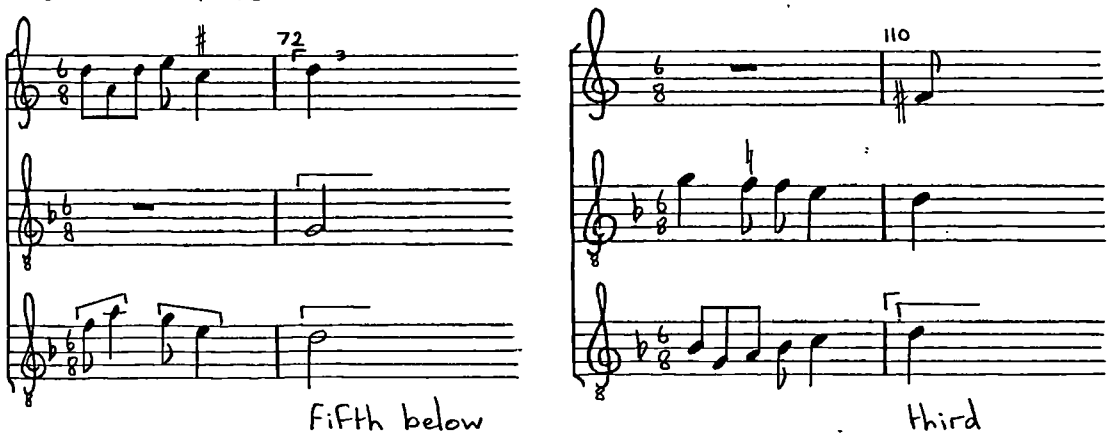
by Dunstable as the range of values is quite large. Leonel, in fact, exhibits the widest range; of his pieces containing dipped cadences, the proportion of octave cadences employing a dip varies from 10% to 75%, whilst for Dunstable the variation is between 25% and 65%. The numbers of these cadences might be of value only in assessing a large sample of music. A more useful marker appears to be the dipped unison cadence. It is characteristic of Dunstable, occurring several times in his music, whereas in Leonel only one example has been found.

Due to the disposition of the tenor in isorhythmic compositions, these pieces employ many overlapping two- and three-part phrases and so a high proportion of their two-part cadences resolve onto a three-part chord. This occurs to a lesser degree in the non-isorhythmic compositions where 8% of Dunstable's two-part cadences are of this type. In Leonel the occurrence is double this, ie. 16%, due to the more fragmentary nature of his duet writing. Example 6 overleaf shows the various types of overlap employed.

In exactly two thirds of cases, Dunstable's added voice is on the same pitch as one of the cadencing voices. In the other instances he adds a fifth above the lower cadencing part. Leonel employs each of these methods in 30% of cases. However, he is more adventurous in the other instances. In 22% he adds a third above the cadence pitch. Dunstable does employ this interval on four occasions in the isorhythmic motets, but not elsewhere.

Example 6 Dunstable Ave regina 24

Leonel Credo 13



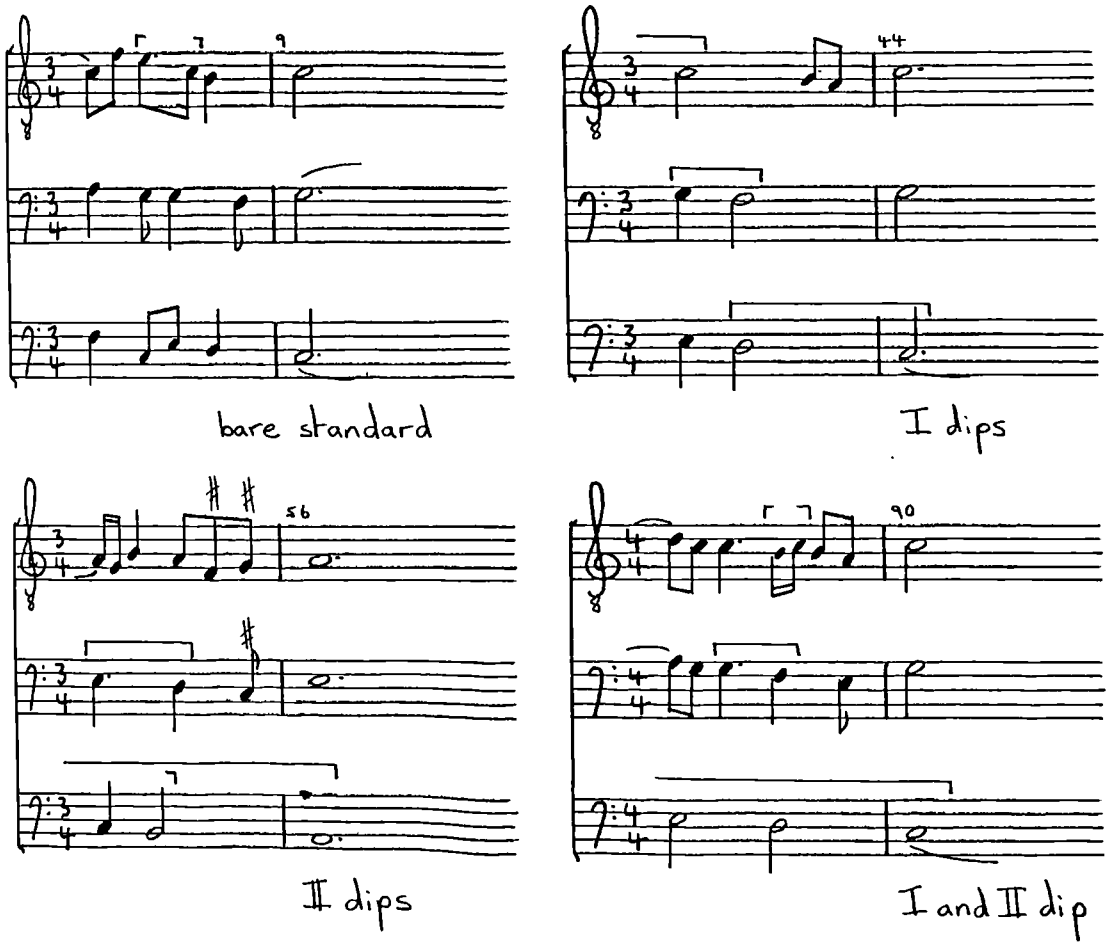
Leonel also employs the unexpected interval of an added fifth below the cadence pitch in 17% of cases.

THREE-PART CADENCES

The addition of a further voice to the two-part formula can produce many harmonic permutations. The one most consistently used during the mediaeval period has often been described. It occurs when the two cadencing voices move outwards to an octave whilst an added inner voice moves stepwise upwards onto the fifth degree above the

final. The sound of this cadence is affected by the species of interval by which the voices move. This is dependent upon the pitch of the cadence and any melodic inflections imposed by a key signature, accidentals or musica ficta. This cadence rarely appears in a bare form but is embellished rhythmically and/or melodically. Often, one or both of the upper voices dips a further degree lower before resolving upwards, as in the two-part writing discussed above. All these cadences will be described as the 'standard' type and are illustrated in Example 7.

Example 7 Dunstable Gloria 2



The distribution of dipped cadences is similar to that in two-part music; they are more frequent overall in Dunstable but the level in individual pieces is more variable in Leonel. In the highest voice of standard cadences they occur in 38% of cases in the former composer and only 28% of cases in the latter. However, the highest level in any one composition is 77% for Dunstable and 100% for Leonel.

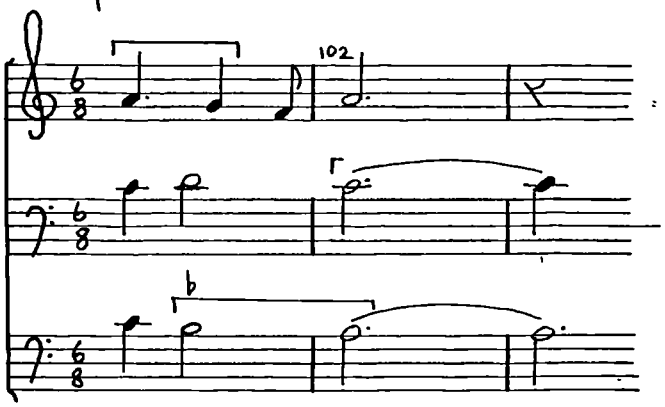
The descant music of Leonel uses this standard cadence type almost exclusively. Two interesting variations which appear only here are shown in Example 8. In the first, voice II remains static during the progression. The second illustrates other cruder forms which do not exhibit stepwise movement to the fifth.

Example 8 Leonel Ave Regina 2

The most common cadence variation occurs when the middle voice moves onto the third degree above the cadence pitch to produce resolution onto an imperfect chord. It is difficult to decide in all cases whether to class this progression as cadential; it may have been used as a

delaying tactic in a deliberate attempt to avoid a cadence by stringing out the phrase for a longer period. In any event, the number of occurrences in each composer is not very different, so does not differentiate between them. Of those cases which do seem to be cadential, there are about one for every twenty-four standard cadences in Dunstable and one for every thirty-two in Leonel (see Example 9).

Example 9 Dunstable Gloria 4



Two other variations on the standard cadence are to be found in the music of Dunstable. The first, as in Example 10, is a delaying of the entry of voice II by a

Example 10 Dunstable Sancta Dei 47

rest at the cadence point. The second, as in Example 11, also delays the resolution of voice II but by an appoggiatura from the note above. He uses the first type five and the second type six times. Leonel uses an appoggiatura of this type on one occasion only.

Example 11 Dunstable Gloria 4

An inversion of the top two voices of the standard cadence produces a formula whereby the parts resolve onto a 12/8 chord (Example 12). This progression appears in roughly equal numbers in the music of Dunstable and Leonel. The same formula is often used to open a phrase.

Example 12 Dunstable Magnificat 36

Another, more advanced, cadence type has been described by other writers. In it, the added voice moves upwards by an octave, crossing the lower cadencing voice and landing again on the fifth degree above the final (see Example 13). The combination of the lower voices gives the illusion of a rising fourth at the bottom of the texture, similar to that in a modern perfect cadence. The progression will be described here as the 'octave leap' cadence. It is a characteristic of Dunstable's style; he employs it on sixteen occasions in his surviving music. Seven of these are in his isorhythmic compositions. The remaining nine are contained in six pieces and occur once for every thirty-seven standard cadences overall. Leonel does employ the cadence twice in his non-descant pieces, that is once for every 128 standard cadences.

Example 13 Dunstable Kyrie I

Even more common are cadences which are more explicitly tonal in shape, though these forms are not usually noted as part of the styles of these composers. Example 14 shows the most frequently-met type in which the

lowest part (often voice II) falls by a fourth. Usually the upper voices retain the octave cadence formula. The resulting chord on the cadence point is reminiscent of the overlapping two and three-part phrases in Leonel discussed above, where he adds a fifth below the cadence pitch. The voices sometimes abandon this movement to produce a true tonal-sounding cadence.

Example 14 Leonel Qvam 26

Another similar tonal-sounding type with a falling fifth in the bottom voice (Example 15) is equally common in Dunstable but there is only one instance in Leonel.

Example 15 Dunstable Sancta 47

Frequencies of these tonal-sounding types compared with that of the standard cadence are:

	octave leap	IV-I	V-I
Dunstable	1 per 37	1 per 68	1 per 68
Leonel	1 per 151	1 per 151	

More rarely, unusual cadences occur which are difficult to classify as they cannot be described by a single formula, taking many different, possibly accidental, possibly experimental, forms. These cadences are not usually mentioned (or conveniently overlooked). However, the aim of this study is not to generalize style but to look for the unusual which may prove helpful in distinguishing individual styles. For example, a rather strange progression has been observed twice in Leonel's music. In Salve Regina CMM50i no.10 b.83 and the Sanctus CMM50ii no.16 b.51, voice II descends by an octave, crossing voice III to produce the illusion of a descending sixth in the bass.

A large proportion of phrases end with none of the cadences described above. For example, two of the voices sometimes move onto a unison as opposed to an octave. The other anomalous instances employ too wide a variety of progressions to mention each one individually, though the most common final chord in these cases is a triad in close position (Example 16). Leonel concludes his phrases more often with a bare fifth (5/1) chord than does Dunstable; fourteen instances have been found, i.e. one in twenty phrases end this way, whereas only one in 145 do so in Dunstable (Example 17). He also tends to use these

Example 16 Leonel Salve 14

Example 17 Leonel Anima 18

miscellaneous endings more often in prominent positions than does Dunstable, although 'prominence' is a difficult concept to measure. There is only one instance of Dunstable ending a section of music in this way.

The proportion of phrases with miscellaneous endings in each attributed composition has been calculated. A phrase is taken to end immediately before a rest in voice I or at the end of a section of music. Whether all such endings are considered or just those landing on a close position triad, pieces by Leonel contain a larger percentage than those by Dunstable (see Tables 26 and 27). 10% or less of these phrase endings is indicative of composition by Dunstable. More than 45% miscellaneous endings or 43% close position endings would indicate composition by Leonel. In both cases, 32% of attributed pieces can be allocated to these areas.

OTHER CHARACTERISTICS OF CADENCES

It is reasonable to suppose that the means of approach to, and quitting of, cadences might exhibit composer-related characteristics. The chords immediately adjacent to those of all standard cadence progressions have therefore been examined.

The chord preceding a standard cadence is nearly always an arrangement of that on the cadence point itself. The most common arrangement is that of a first inversion triad, producing a stepwise descent to the cadence point in voice III. However, in a small proportion of cases the arrangement is identical to that on the cadence point, as in Example 18. This is almost twice as common in

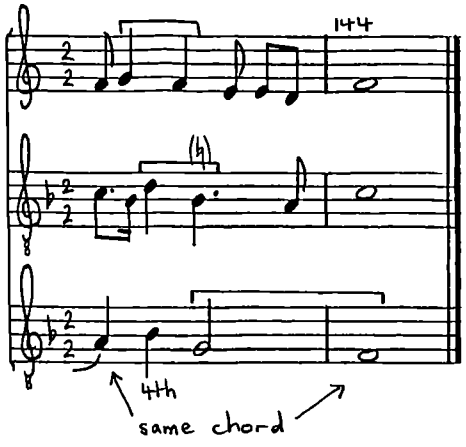
Example 18 Dunstable Gloria 9

Dunstable, occurring in 13% of cases as opposed to 7% of cases in Leonel. The progression is associated with final cadences at the end of sections of music, especially in Dunstable. In this composer 29% of final cadences are approached in this way as opposed to 12% in Leonel. The

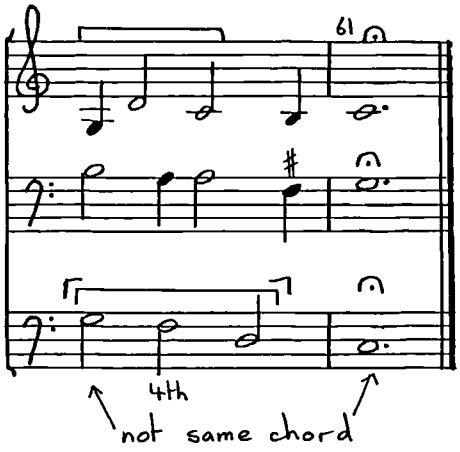
progression is to be found in 42% of compositions by Dunstable and 17% of those by Leonel.

Less commonly, the chord immediately preceding the cadence is based on the fourth degree above the cadence pitch. In Dunstable this chord is always an insertion between the normal antepenultimate and penultimate chords. In Leonel, the approach via the fourth degree is slightly more frequent (14% of standard cadences as opposed to 12% in Dunstable) and appears more often in prominent positions (24% of end-of-section cadences as opposed to 17% in Dunstable). However, the most distinguishing characteristic in Leonel is that a third of these instances are not preceded by the usual chord on the cadence pitch. 39% of his pieces contain at least one instance of this atypical preparation (Example 19).

Example 19 Dunstable Crux 39

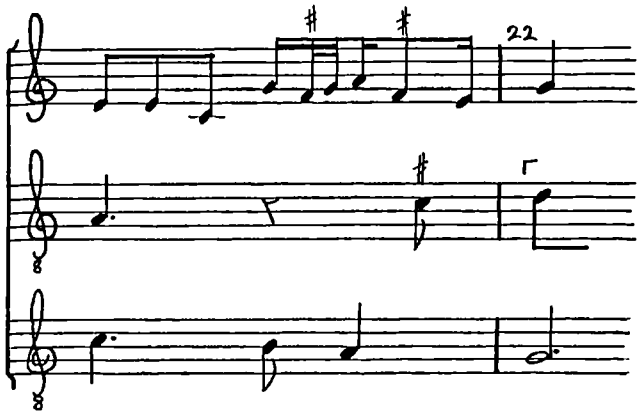


Leonel Sanctus 20



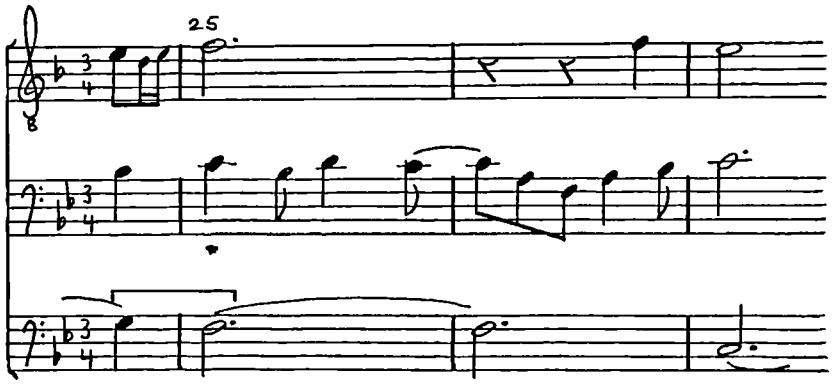
Occasionally, the antepenultimate chord consists of two notes only, there being a rest in voice II. This is four times as common in Leonel, occurring in about 8% of cadences, as opposed to only 2% in Dunstable (Example 20).

Example 20 Leonel Credo 19



A cadence is often followed by a chord containing an octave between voices II and III. This is approached by voice III from the cadence point in a descending movement of any interval between a second and a fifth. The two chords are sometimes separated by a rest in voice I, and then voice II often provides a decorated melodic link between them. The progression happens a little more often in Dunstable than in Leonel (once in every five standard cadences as opposed to once in every eight). Also, the progressions in Dunstable are more prominent and standardized to the typical pattern (see Example 21).

Example 21 Dunstable O Crux 53



In Leonel, voice III often also supplies intervening decorative notes and the rest in voice I appears less often; only seven examples can be found with a rest and no decoration in voice III, as opposed to thirty-five in Dunstable.

The periods between cadences vary in length. No standard phrase length exists, although the average period varies according to the piece - some tend to have consistently short, others consistently long phrases. As this could be a factor in individual styles, the spacing of cadences has been calculated for each piece. This has been performed both in terms of the average number of chords per cadence and the average length in minims between cadences. Both methods show that cadences are, on average, closer together in Leonel, although the latter method produces a slightly clearer separation between the two composers and so is used for the figures shown in Table 28. The calculations are based on all possible cadence types including standard progressions in any position, more unusual progressions which occur at phrase endings and two-part cadences in the primary and secondary categories. Less than 15.7 minims per cadence indicates composition by Leonel while more than 28.5 minims per cadence indicates composition by Dunstable. 39% of attributed pieces lie in these areas. In several instances, cadences are so close in Leonel that the cadence point of one serves as the antepenultimate chord of the next.

FOUR-PART CADENCES

Composition in four parts allows for a greater number of permutations of position for the voices. A fourth part can duplicate one of the other three at the unison or octave. Alternatively it can supply a third in the final chord, producing a fuller, more modern-sounding harmony. The proportion of cadences in four-part music which are based on a full triad is therefore greater than in three parts.

THE DEVELOPMENT TOWARDS TONALITY

In addition to fulfilling the objective of differentiating the music of Leonel and Dunstable, this study has provided an insight into the development of the cadence during their lifetimes. Because of its presence in the Old Hall manuscript, there is good reason to presume that the descant music of Leonel is the earliest under consideration. The cadence is seen to develop from a purely modal form as used in these works into a period of experimentation and diversification in the later works of Leonel and those of Dunstable. Amongst the experiments appear the first tonal forms. Dunstable, the younger man, employs these more frequently than Leonel.

The case of the octave leap formula is especially noteworthy. It provides a link between the modal standard cadence, from which it retains stepwise contrary motion

onto the octave, and the tonal perfect cadence with true movement by an ascending fourth in the bass. Its lifespan seems to have been limited to only a few decades, reaching its height in the Burgundian period.[44] The levels of this cadence might, then, be a valuable dating factor. Although not within the scope of this thesis, a more detailed study of other composers' work in this respect could prove interesting.

Following an article by Caldwell which traces the beginnings of tonality back to around 1400 in England and examines key schemes in a composition by Dunstable,[45] it was hoped that analysis in terms of pitch organization might provide information useful to this thesis. However, despite careful cataloguing of all cadence pitches and analysis of the data in several different ways, no evidence could be found that the choice of pitches or the sequence of pitches used for cadences differs between the two composers. Nor can it be said that any consistent tonal organization was observed. Though Caldwell thought the term 'modulation' could be appropriately used in connection with this period, this present study will, more cautiously, describe cadences as being merely 'on' a certain pitch. Modulation implies a more systematic organization of tonal structure and chord hierarchy than can be demonstrated here.

[45] John Caldwell: 'Some Aspects of Tonal Language in Music of the Fifteenth and Sixteenth Centuries' in PRMA, vol.110 (1983-84), pp.1-24.

One small fact emerging from the investigation is that Dunstable does use the same pitch in succession more often than Leonel. Measured in terms of three-part standard cadences only, around 15% of cadences in Dunstable repeat the previous pitch, as opposed to 10% in Leonel. It is doubtful whether this difference is large enough to be of great value in differentiating individual pieces and certainly could not be used in isolation as evidence of authorship, yet may furnish additional corroborative evidence in combination with other facts.

APPENDICES

PART ONE

APPENDICES

THE COLLECTED DATA

The information which has been amassed during the course of this project would fill several volumes; it would be impossible and unnecessary to reproduce all of it here. However, the following appendices contain, in abbreviated form, some of the most basic statistics collected. Many of the more complex data have been derived from these fundamental figures, and it is almost certain that further conclusions could be drawn from them, relevant to topics which have not been investigated during this study. They are included here in the hope that they will prove useful to future workers. The chord analysis information has been restricted to non-descant and non-isorhythmic three-part compositions.
