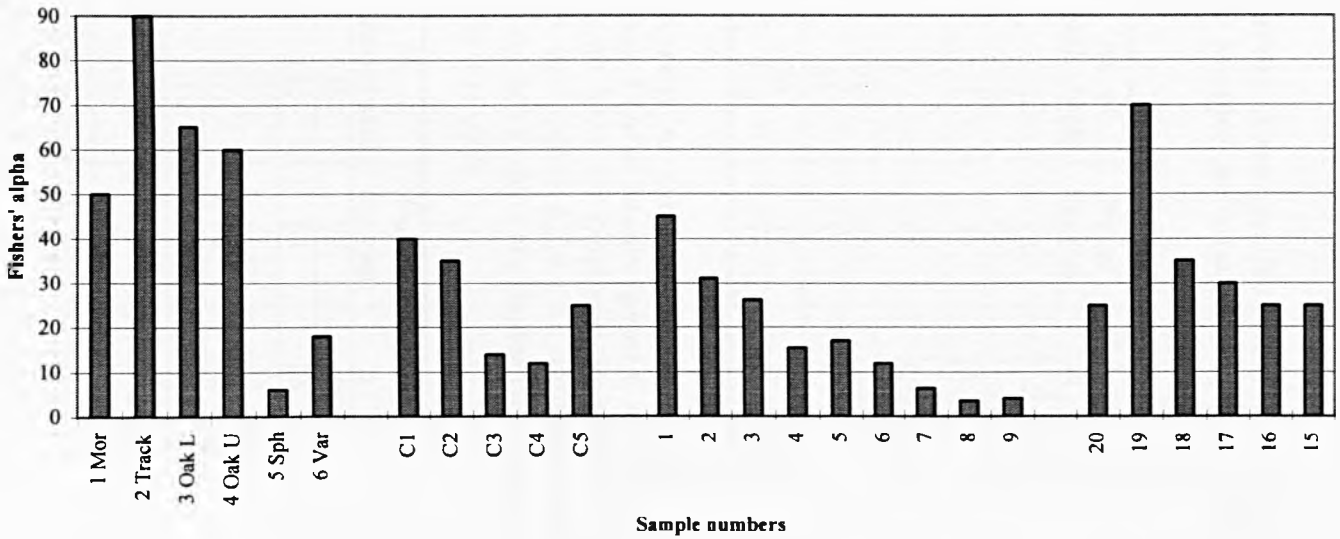
15	68	33	25

Figure 8.3; Faunal diversity calculated for all palaeoentomological samples from Thorne Moors (points A-D, Figure 4.3) (Data below)



Measure of faunal diversity of samples calculated for Buckland's (1979) samples from Thorne Moors (point A on Figure 4.3). Samples are not arranged chronologically:

Sample	No. of individuals	No. of Species	Fisher's α
1 Mor	42	30	50
2 Track	825	205	90
3 Oak L	763	163	65
4 Oak U	274	104	60
5 Sph	588	29	6
6 Var	49	24	18

N.B. Species numbers have been estimated.

Measure of faunal diversity of samples from Roper (1993, 1996), (point B on Figure 4.3). The samples are arranged stratigraphically, sample 1 denoting the deepest:

Sample	No. of individuals	No. of Species	Fisher's α
1	101	53	45.0
2	220	65	31.1
3	131	47	26.3
4	93	30	15.4
5	62	27	17.0
6	94	26	11.9
7	87	17	6.3
8	76	11	3.5
9	100	13	4.0

Measure of faunal diversity of samples calculated for Whitehouse's (1993, 1997) samples from Thorne Moors (point C on Figure 4.3).
N.B. Samples C1-C5 came from the same sampling location, but are not arranged chronologically. See section 8.2.4.4 for additional details. Samples B1-B3 came from *Pinus* rot holes; diversity figures have not been calculated because of the low figures involved.

Sample	No. of individuals	No. of Species	Fisher's α

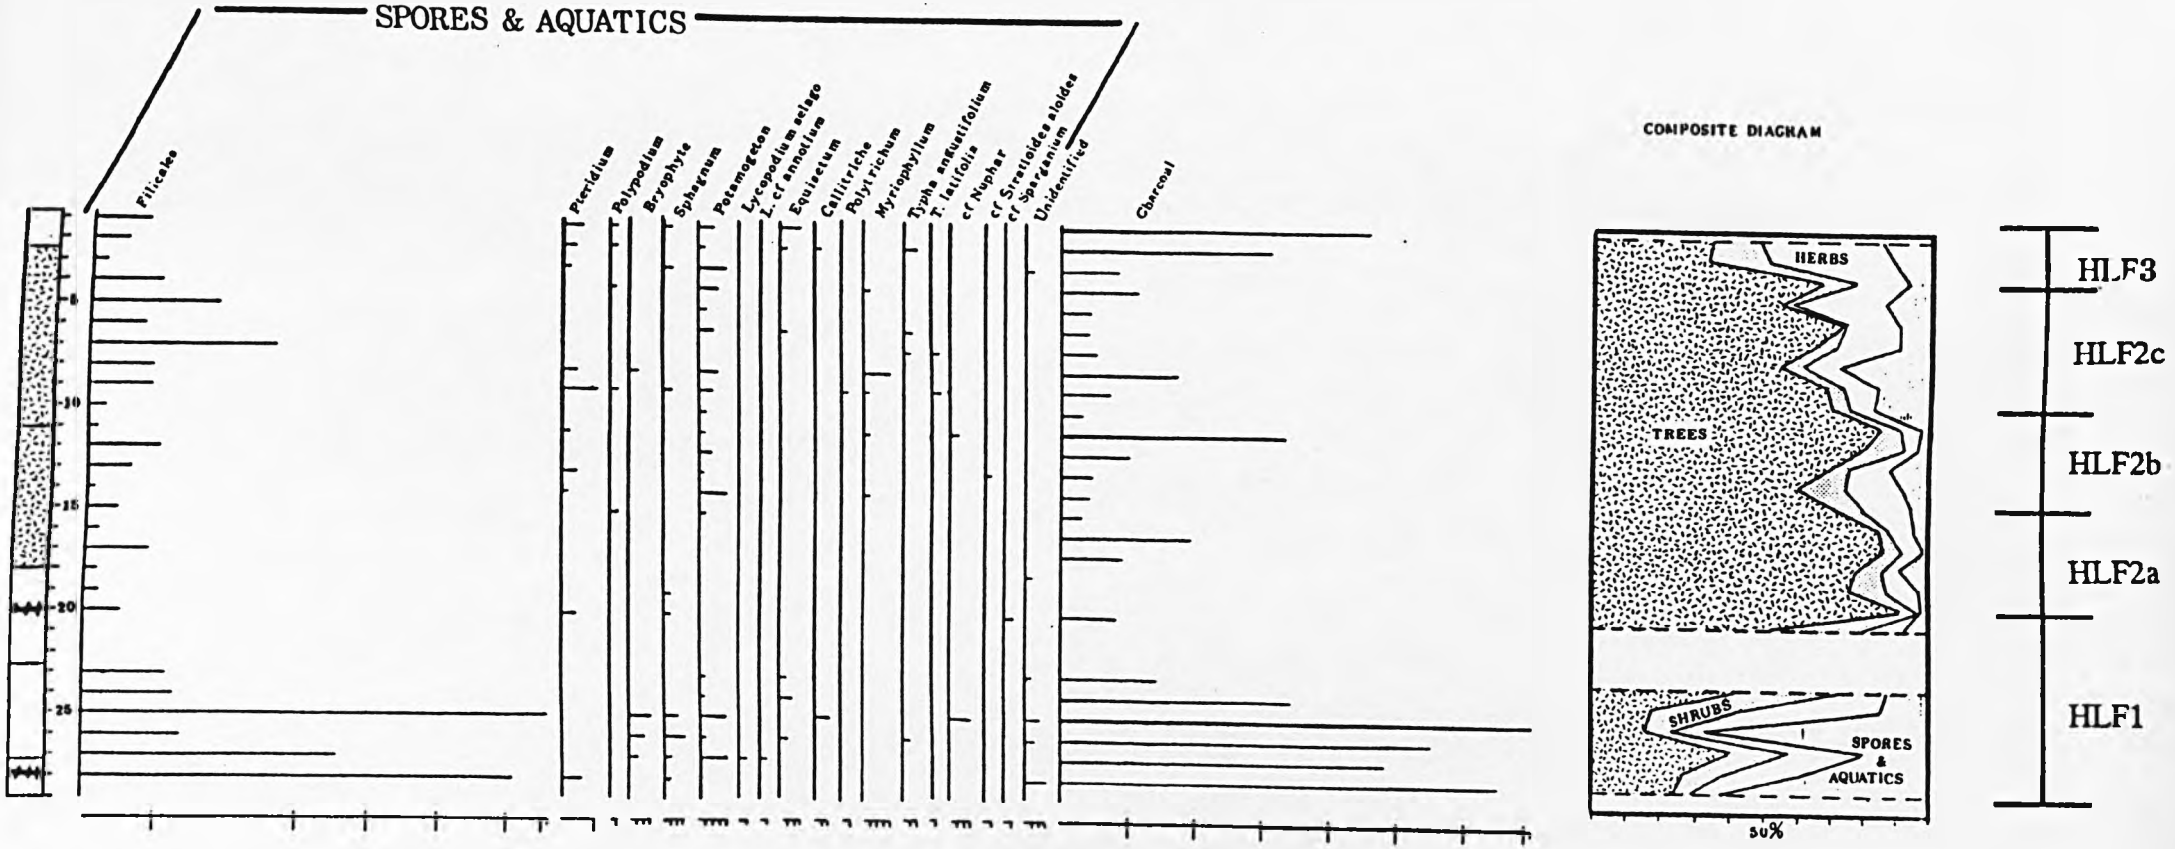

Figure 11.1; Klinger's (1996) Bog Climax Theory, where peat formation occurs as a result of both terrestrialisation and paludification.

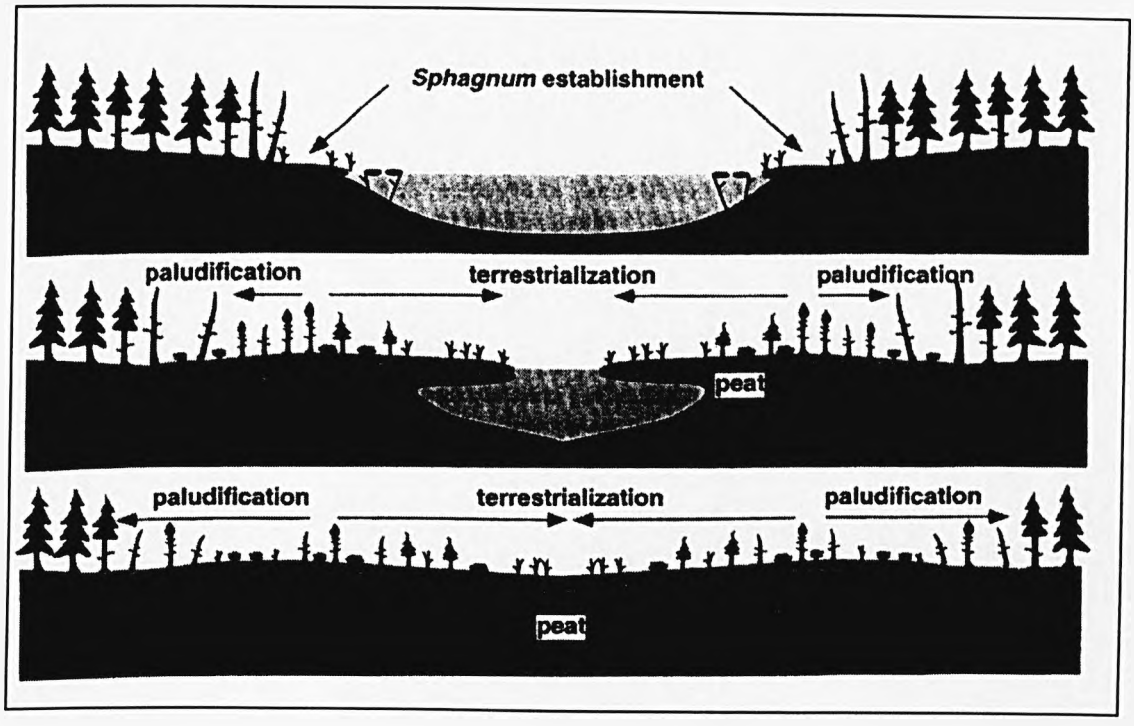

Figure 11.2; Flow diagram indicating the development of the landscape of the Humberhead Levels, after Buckland and Sadler (1985).

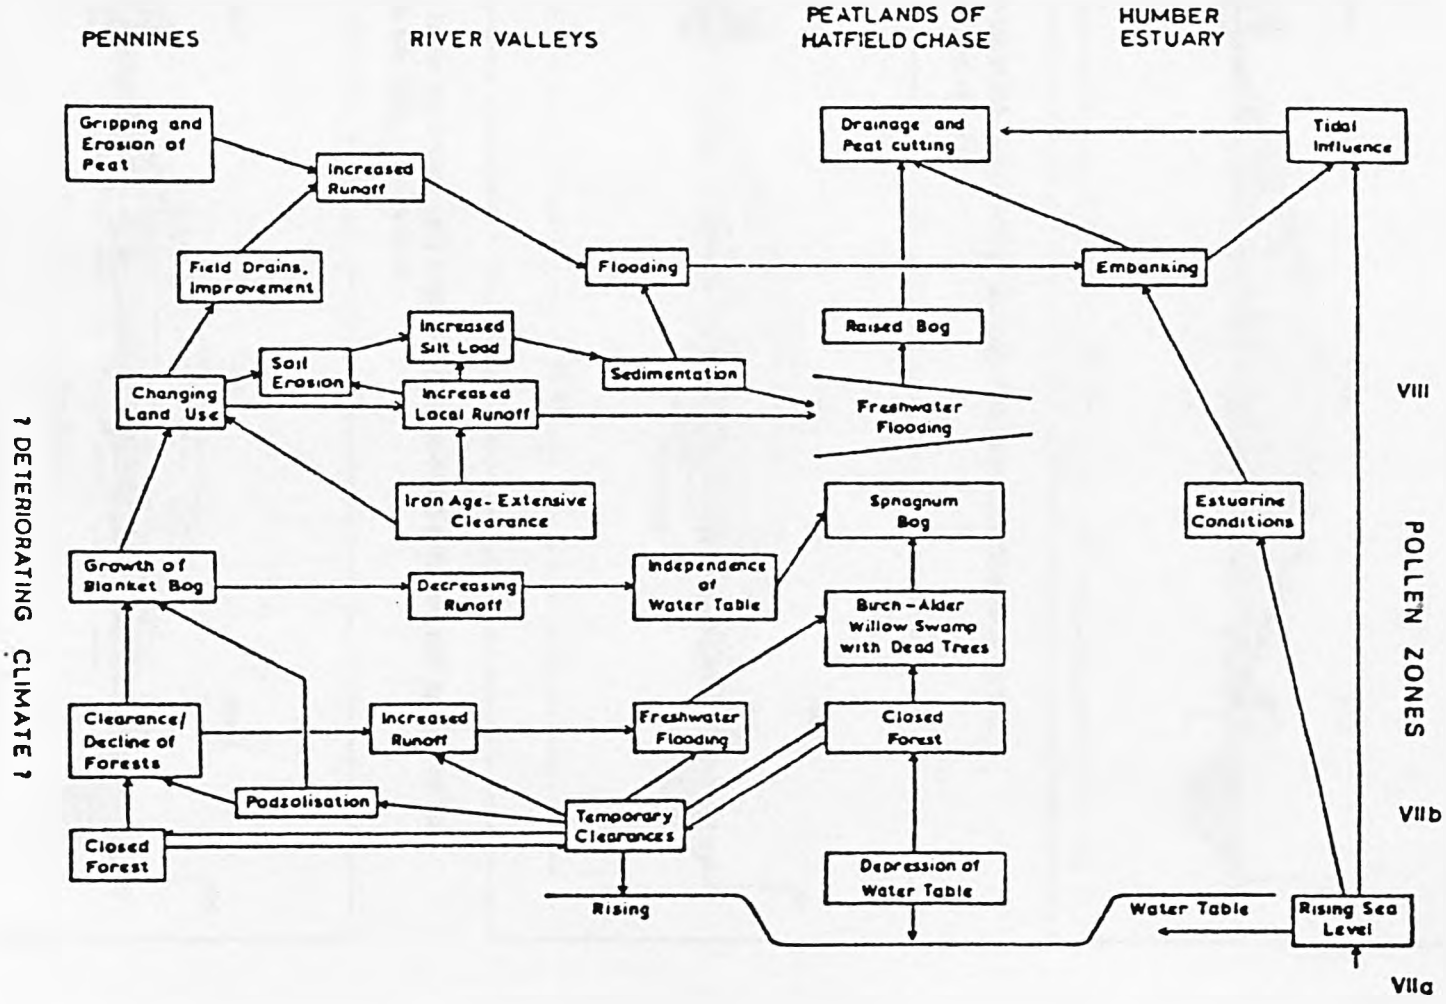

Figure 11.3; Models of mire initiation proposed by Buckland and Smith (*in press*) (drawings by P.C.Buckland)

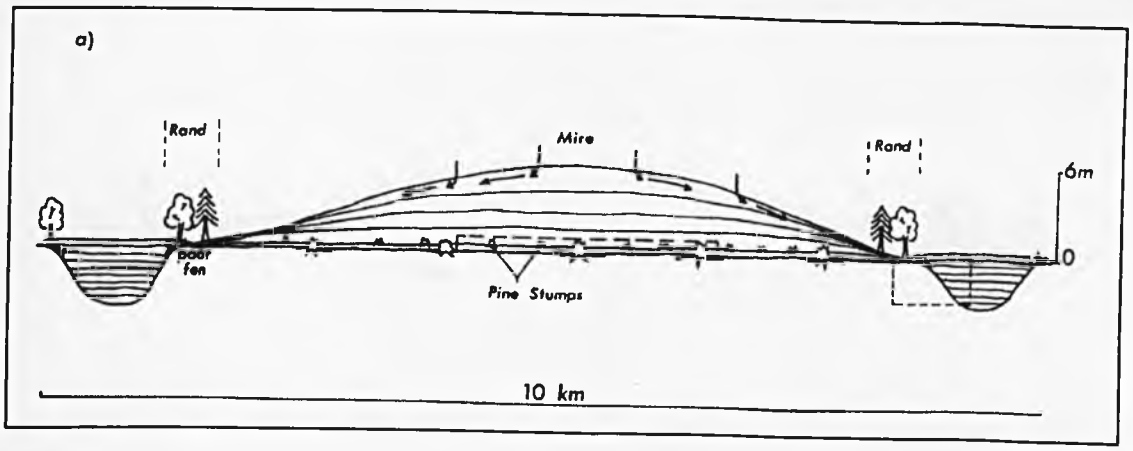
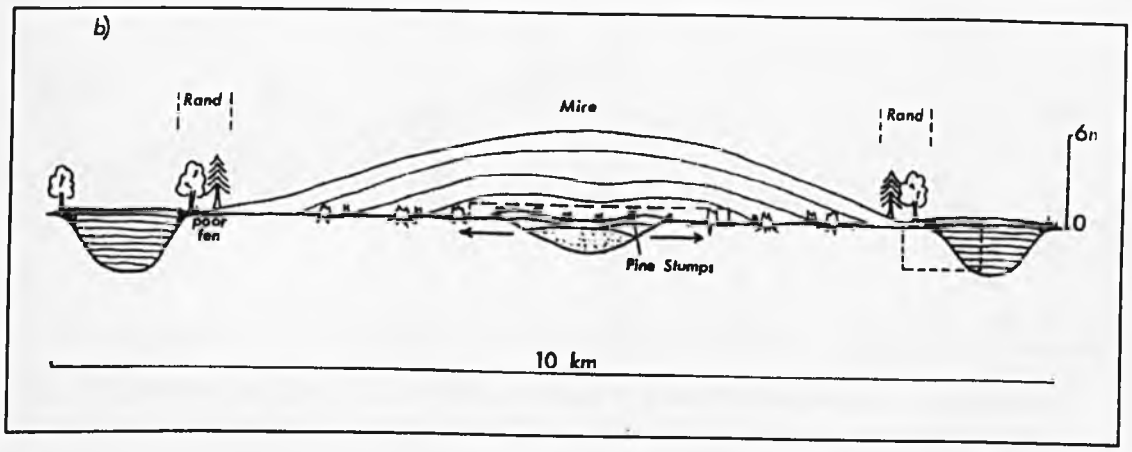
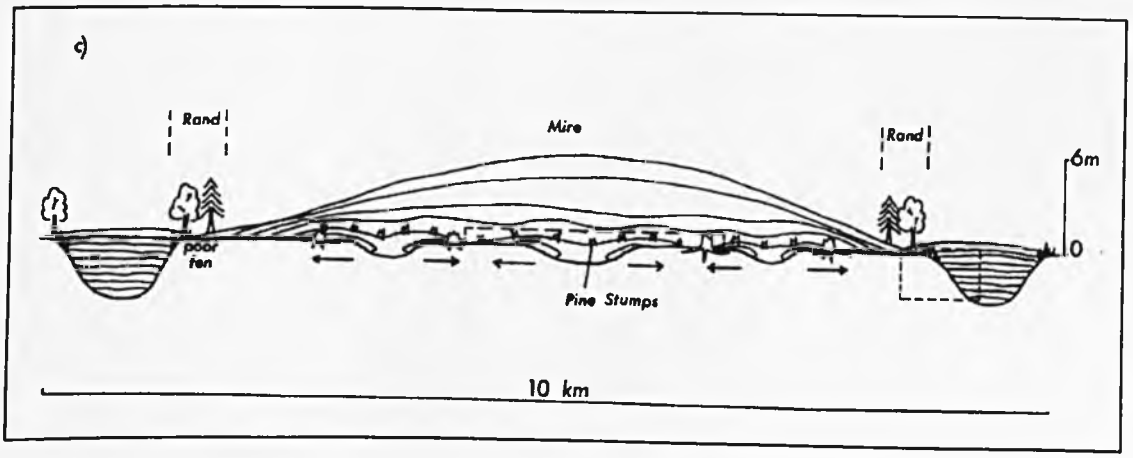


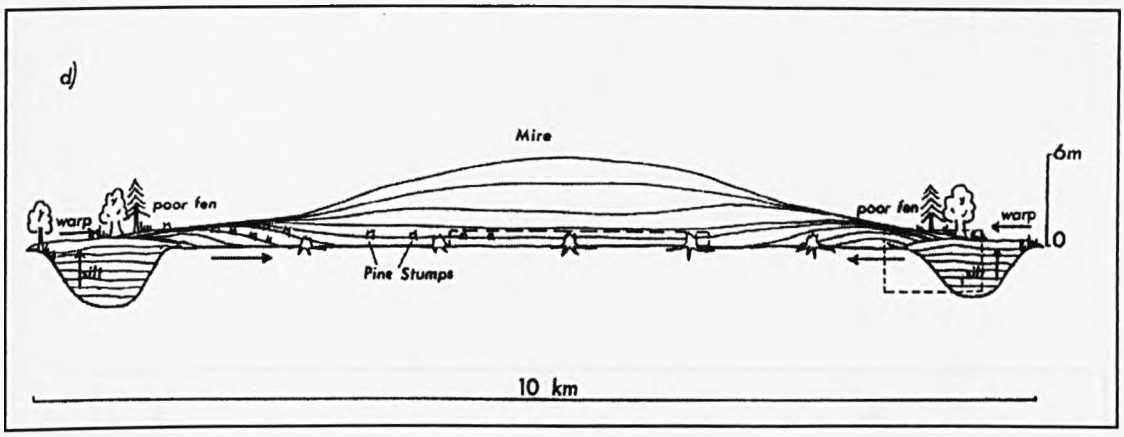
a. Rising water-table leads to widespread paludification, leading to poor fen, acidification and raised mire.

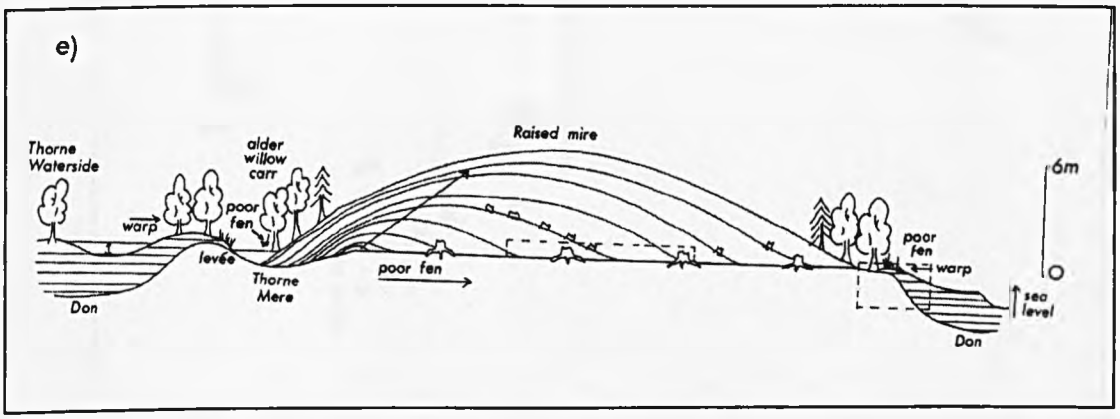


b. Infilling of a basin by limnic sediments leads to terrestrialisation and growth of fen, to poor fen from the margins of a lake.



c. A poly version of (b), with several small ponds rather than lakes forming on the forest floor. The developing poor fen communities lead to raised mires and eventually coalesce into larger raised mire.





d & e. Progressive infilling of river channels leads to paludification from the margins of a river or mere, progressing inwards towards its "core" (d) or laterally until confined by slope or a more active nutrient-rich environment (e).

Latest fossil date: > 3350-3100 cal BC.

TABLES

Table 5.1; Preservation Index for Coleoptera.

0. Blank	No insect remains present in the sample
1. Very poor	Only the most robust, highly sclerotised taxa (i.e. Ground beetles and Weevils) present, these eroded and testaceous. Identification can be expected only to genus level.
2. Poor.	Testaceous, even amongst more robust groups, and the more weakly sclerotised taxa eroded. Some identification to species level may be expected.
3. Moderate.	Poorly sclerotised groups are testaceous and there will be some erosion of chitin but identification to species level is usually possible. Setae may be evident upon pubescent species.
4. Good.	Well-sclerotised with little evidence of erosion, but large or brittle elytra still fragmented. Setae preserved on pubescent species. A range of Diptera preserved, including wings.
5. Excellent.	Complete, well-sclerotised remains often with some parts still articulated. Complete elytra may be expected even in larger specimens. Good preservation of colouring and setae.

Table 5.2; Habitat categories

Woodland/trees

1. Pinewoods/heaths	This includes those species which are associated with pinewood and heaths, such as *Dromius augustatus* and Scolytidae such as *Tomicus piniperda, Hylastes opacus.* It does not include any dead wood feeders.
2. Deciduous woodland	Includes those woodland species associated with broad-leaved woodland. Generally associated with live parts of trees, rather than dead wood and includes leaf miners such as members of the genus *Rhynchaenus.*
3. Woodlands (all types)	This includes species which live in all types of trees and whose preference is more wide-ranging.
4. Dead and decaying tree habitats (coniferous).	Includes specialists which feed on rotting, mouldy bark, particularly characteristic of late successional habitats, exclusively associated with coniferous trees (e.g. *Ostoma ferrugineum*; *Rhyncolus ater*).
5. Dead and decaying tree habitats (deciduous).	As above (4), but associated exclusively with deciduous trees (e.g. *Cerylon ferrugineus*; *Dryophthorus corticalis*)
6. Dead and decaying tree habitats (all types).	Includes species whose preferences are more wide-ranging than those above, including both coniferous as well as deciduous trees (e.g. *Rhyncolus punctulatus*).
7. Woodland/flowers/herbs	Species which typically live in open areas of woodlands or at woodland margins and which often feed upon flowers and herbs (e.g. *Dascillus cervinus*; *Xylocleptes bispinus*).
8. Woodland/fungi & mouldy plant debris	Includes those species which are often associated with bracket fungi on wood, such as *Polyporus* spp., but which can also be found in plant litter/moss (e.g. *Aspidophorus orbiculatus*).

Damp woodland

9. Damp woodland (e.g. *Alnus* carr)	Species which commonly live in humus-rich, damp deciduous woodland, often in places such as *Alnus* and *Salix* carr (e.g. *Chrysomela aenea, Nebria brevicollis, Carabus granularis*).

Heath and grassland

10. Sandy heath/*Calluna*	Species associated with sandy substrates and heathland/moorland, often feeding on *Calluna vulgaris* (e.g. *Bradycellus ruficollis*; *Micrelus ericae*). This category overlaps with cat.1.
11. Heath/woodlands	Species which are found in both heath and woodland, but excludes coniferous species, which are included within pinewoods/heaths. It includes species such as *Rhamphus pulicarius*.
12. Xerophilous	Species which prefer dry places, such as dry heath, sandy or gravelly areas, sandy shores and dunes. Includes species that could not be accommodated within the two previous categories.
13. Grassland, herbs & flowers	Species which live in grassland and herbs, in open situations, such as members of the genera *Apion, Sitona*, some Chrysomelidae and Nitidulidae.

Non-acid wetlands

14. Non acidic bogs/wetlands	Fairly eurytopic species found in a variety of wet biotopes, including peatlands and fens, but not considered obligate oligotrophic taxa (e.g. *Agonum fuliginosum*, *Pterostichus diligens*; *Trechus rivularis*).
15. Fens/reeds and sedges	Includes those species which are typically found in fens or more nutrient rich wetlands on emergent vegetation (e.g. members of the genus *Donacia, Plateumaris sericea*).
16. Non-acid/plant debris	Includes those species which are less tolerant of very oligotrophic conditions (e.g. *Olophrum piceum*).
17. Reeds/brackish water	Includes species which live on reeds in brackish water (e.g. *Plateumaris braccata*).

Acid wetlands

18. Acid bogs	Includes those species particularly associated with peat bogs and *Sphagnum* habitats, which are obligate oligotrophic taxa (e.g. *Bembidion humerale*; *Agonum ericeti*).
19. Acid bogs / *Eriophorum* & *Sphagnum*	Includes those species which are typically associated with acid loving vegetation (e.g. *Plateumaris discolor*).
20. Bogs/plant debris	Includes those species which are found in all types of bogs, but which are more acid tolerant than category 16 (e.g. *Acidota crenata*).

Hygrophilous

21. Hygrophilous	Includes many of those more "generalist" species, which are wet-loving but which live in a variety of habitats (e.g. *Dyschirius globosus*; *Bembidion* spp.; *Pterostichus* spp.).
22. Hygrophilous/plant debris	Includes species which are wet loving which live amongst plant debris, for instance *Trechus rubens, Stenus* spp. and *Lathrobium* spp.
23. Water margins/river banks	This category includes those species which live in the littoral zone and includes those species which live on river banks (e.g. *Elaphrus cupreus*; *Bembidion schueppeli*).
24. Water margins/plants & mud	Includes species which reside in the littoral zone of pools/streams/rivers. Many species live in detritus and flood debris, as well as burrow in mud and algae detritus (e.g. *Bledius* spp.; *Bembidion guttula*).
25. Wet locations/ herbs & marsh plants	Includes species which live in wet locations on marshy plants.

Aquatics

26. Aquatic/generalists	Aquatics (species which spend most of their adult life under water) which are found in many different types of water (e.g. *Agabus bipustulatus*; *Ilybius fuliginosus*; *Colymbetes fuscus*).

27. Aquatics/bogs	Aquatics which are found on all types of bogs, including those tolerant of a range of acidic conditions (e.g. *Hydroporus* spp.; *Hydroporus scalesianus*).
28. Aquatic/acid bog	Aquatics which are associated only with typically acid conditions (e.g. *Hydroporus gyllenhali*; *Hydroporus tristis*).
29. Aquatic/non acidic bog	Aquatics found in fen and other non-acidic conditions (e.g. *Hydraena testacea*; *Limnebius aluta*) and which are not tolerant of acidic conditions.
30. Aquatic/vegetation & detritus rich	Aquatic species which enjoy living in habitats with plenty of vegetation and detritus (e.g. *Ochthebius minimus*; *Anacaena globosus*) as well as those living in vegetation rich standing and slow moving waters.
31. Aquatic/stagnant & sometimes brackish water	Species which live in stagnant water, sometimes also brackish, such as *Noterus clavicornis* and *Haliplus confinis*.
32. Aquatic/slow moving water	Aquatic species which are associated with very slow moving water (e.g. *Ochthebius bicolon*; *Graptodytes pictus*).
33. Aquatic/running water	Aquatic species which are associated with running water (e.g. *Limnebius truncatellus*; *Gyrinus aeratus*), often clear.

Decaying debris

34. Exclusively dung	Species which are associated exclusively with dung (e.g. many members of the genus *Aphodius*). N.B. this category was only utilised in the analysis of the floodplain sequences.
35. Decaying animal and plant debris	Includes those species found commonly in dung and other animal debris (e.g. carrion) as well as in other rotting organic material. (e. g. *Cercyon* spp.; *Platydracus fulvipes*; *Aphodius* spp). Fouler than the next category.
36. Fungi/plant debris	Includes species which live in mouldy and rotting plant debris, such as some members of the Lathridiidae & Cryptophagidae families.
37. Fungi/wood/plant debris	Includes those species which live under mouldy fungoid wood as well as plant debris (e.g. *Dienerella separanda*).

Fire species

38. Fire indicators	Species which are noted in the literature as being attracted to fire (pyrophilous). N.B. This category is additional to any of those above and all species in this category belong to one of the main habitat categories.

Unclassified

UN Unclassified	This includes individuals whose identifications which were not close enough to enable them to be categorised .

Data from Smith (1985), unless otherwise indicated. New dates obtained for this research are coded SRR-** or Beta **. This table was originally devised by P.C. Buckland (in Smith, *in press*), to whom due acknowledgement is made, with additions by the author.

Note: Depths for sites on Thorne and Hatfield Moors are below the cutting surface at the time of sampling in the late 1970's, before large scale milling of peat, except recent dates, which reflect depths recorded in 1995.

Table 6.1; Radiocarbon dates from Hatfield Moors (data as per Table 5.3).

* = dendrochronological date.

Table 7.1; Chronology of palaeoentomological samples from Hatfield Moors (dates expressed as BC). All dates are calibrated, except dendrochronological dates, which are prefixed by an asterix *. Uncalibrated radiocarbon dates are included in brackets. Broad-span dates are assessed upon the longest range possible. The term "phase" is used not to denote vegetational phases, but rather to allow groups of sites/samples to be placed together.

Period	Phase	Site/samples	Dominant vegetation as indicated by insects.	Trophic stage
***3618 to 3418 BC**	**1**	Tyrham *Quercus* woodland	Damp *Quercus* dominated woodland.	? Rheotrophic
***c.* 3,300-2445 BC**	**2**			
*2921 to 2445 BC	2	Tyrham *Pinus* woodland	*Pinus/Calluna* heath, with *Quercus*, *Fraxinus*, *Betula*, *Fagus* and *Alnus*	Mesotrophic, grading into ombrotrophic.
c. 3350-2930 cal BC (4480 ± 45 B.P.) and later.	2	Base of HAT 3 *Pinus* woodland.	*Pinus/Calluna* heath with *Quercus*, *Fraxinus*, *Fagus* and *Alnus*.	Mesotrophic, grading into ombrotrophic.
c. 2900-2350 cal BC (3990 ± 60 BP) and later	2	60 cm. from base of LIND B.	Wet *Calluna* heath.	Largely ombrotrophic.
***c.* ? cal 2,000 BC**	**3**			
c. ? 2,000 BC and later (or 3,500 BP)		Base of LIND A. Rough date obtained on stratigraphic grounds. Top of sequence unknown.	Wet *Pinus* heath, turning into *Calluna* heath.	Mesotrophic
***c.* 1520-1390 cal BC to *c.* 1,300 BC**	**4**			
1520-1390 cal BC (3165 ± 40 BP)		Base of HAT 4 (insect assemblage zone 1). End of zone dated upon beginning of next zone.	*Pinus* woodland with *Quercus*, *Fagus*, *Fraxinus* and *Alnus* carr communities	Rheotrophic
***c.* 1,300 to 1,000 cal BC**	**5**			
1390-1030 cal BC to 1320-930 cal BC (2965 ± 45 BP and 2960 ± 45 BP)		HAT 4 Insect assemblage zone 2. Centred around ? possible recurrence horizon (Smith's [1985] HHL V).	*Pinus* heath, becoming increasingly waterlogged, with fen and ombrotrophic indicating taxa.	Mesotrophic.
***c.* 1,000 cal BC to 700 AD**	**6**			
1130-840 cal BC (2820 ± 50 BP)		Top of LIND B sequence.	Ombrotrophic mire with wet heath elements.	Ombrotrophic.
1420-1120 cal BC to 560-680 cal BC (3020 ± 45 BP and 1405 ± 45 BP).		HAT 4 insect assemblage zone 3, dates from top and bottom of zone.	Ombrotrophic mire with wet heath elements	Ombrotrophic.

Table 9.2; List of species included in CANOCO analysis, including abbreviated names which appear in plots (N.B. Species are not in taxonomic order. Their order is determined by the number of samples each species occurred in, sorted in numerical order).

Species	Abbreviated name
Bradycellus spp.	Bradyc
Ilybius aenescens Thom.	Ilaenesc
Ilybius spp.	Ilybius
Agabus/Ilybius sp.	Ag/Il
Colymbetes fuscus (L.)	Colfusc
Enochrus spp.	Enochrus
Agathidium sp.	Agath
Xantholinus linearis (Ol.)	Xanlin
Atrecus affinis (Payk.)	Atraffin
Othius myrmecophilous Kies.	Othiusmy
Erichsonius cinerescens (Grav.)	Erichscin
Mycetoporus sp.	Mycetop
Atomaria spp.	Atomaria
Phalacrus caricis Strm.	Phalcar
Cerylon histeroides (F.)	Ceryhist
Dryocoetinus villosus (F.)	Dryovill
Ceutorhynchus spp.	Ceutorhy
Trechus obtusus Er./ *4-striatus*	Tobtusus
Bradycellus harpalinus (Serv.)	Bradyhar
Hydroporus longulus Muls.	Hylong
Agabus affinis (Payk.)	Agaffin
Helophorus spp.	Heloph
Silpha atrata L.	Silphatr
Stenus kiesenwetteri Rosen.	Stkiesen.
Paederus spp.	Paederus
Gabrius spp.	Gabrius
Bryaxis curtisi (Leach)	Brycurt
Pselaphus heisei (Hbst.)	Pselheis
Denticollis linearis (L.)	Dentlin
Melasis buprestoides (L.)	Melasis
Chrysomela aenea L.	Chryaen
Altica britteni Sharp	Altbritt
Altica sp.	Altica
Phyllobius sp.	Phyllob
Dryophthorus corticalis (Payk.)	Dryocort
Hydroporus gyllenhali Schdte.	Hygyll
Hydraena testacea Curt.	Hydrtest
Stenichnus collaris (Mull.)	Stencoll
Lathrobium rufipenne Gyll.	Lathrufi.
Lathrobium longulum Grav.	Lathlong
Ochthephilum fracticorne (Payk.)	Ochfract
Dalopius marginatus (L.)	Dalomarg
Scolytus ratzeburgi Jans.	Scolratz
Tomicus piniperda (L.)	Tompini

Rhyncolus sculpturatus Walt.	Rhynscul
Lathridiidae indet.	Lathrid
Bembidion spp.	Bembid
Cercyon spp.	Cercyon
Lathrobium terminatum Grav.	Latherm
Rhamphus pulicarius (Hbst.)	Rhpulic
Pterostichus spp.	Pterost
Hydraena britteni Joy	Hydbrit
Ochthebius spp.	Ochtheb
Limnebius aluta Bed.	Limaluta
Coelostoma orbiculare (F.)	Coelorbi
Enochrus affinis (Thun.)	Enocaff
Olophrum fuscum (Grav.)	Olofusc
Corticaria spp.	Cortic
Rhyncolus elongatus Gyll.	Rhynelon
Dyschirius globosus (Hbst.)	Dyscglob
Philonthus/ Quedius spp.	Phil/ Qu
Grynobius planus (F.)	Gryplan
Scolytidae gen. et sp. indet.	Scoly
Quedius spp.	Quedius
Microcara testacea (L.)	Micrtest
Plateumaris spp.	Plateum
Rhynchaenus rusci (Hbst.)	Rhyrusci
Bradycellus ruficollis (Steph.)	Bradrufi
Pterostichus minor (Gyll.)	Ptminor
Hydroporus tristis (Payk.)	Hytrist
Hydroporus melanarius Strm.	Hymel
Acidota crenata (F.)	Acrenata
Lathrobium fulvipenne (Grav.)	Lathfulv
Rhynchaenus quercus (L.)	Rhyquerc
Agonum obscurum (Hbst.)	Agobscur
Hydroporus scalesianus Steph.	Hyscales
Lesteva heeri Fauv.	Lestheer
Apion spp.	Apion
Rhyncolus chloropus (L.)	Rhychl
Cercyon convexiusculus Steph	Cercconv
Megasternum obscurum (Marsh.)	Megaobsc
Lathrboum brunnipes (F.)	Lathbrun
Philonthus spp.	Philont
Bryaxis bulbifer (Reich.)	Bryabulb
Aphodius spp.	Aphodius
Rhynchaenus spp.	Rhynchae.
Ochthebius minimus (F.)	Ochtmin
Hydrobius fuscipes (L.)	Hydfusc
Plateumaris discolor (Panz.)/ *sericea* (L.)	disc/ser
Plateumaris sericea (L.)	PlatSer
Agabus bipustulatus (L.)	Agbip
Micrelus ericae (Gyll.)	Micreric
Bryaxis spp.	Bryaxis

Plateumaris discolor (Panz.)	Platdisc
Agabus spp.	Agabus
Agonum fuliginosum (Panz.)	Agonfuli
Anacaena globulus (Payk.)	Anacglob
Cyphon padi (L.)	Cyphpadi
Olophrum piceum (Gyll.)	Olopic
Pterostichus nigrita (Payk.) / *rhaeticus*	Ptnigrit
Lathrobium spp.	Lathrob
Pterostichus diligens (Strm.)	Ptdilig
Aleocharinae gen. et sp. indet.	Aleoch.
Stenus spp.	Stenus
Cyphon spp.	Cyphon
Hydroporus spp.	Hydrop

Table 10.1; Coleoptera list from Hayfield Lodge Farm, Rossington (* denotes non-British species)

	20	19	18	17	16	15	14	10	7	5	3	1

* Species is on the current British list but is commonly believed to be an introduction earlier this century. Since this ground beetle is unlikely to have been overlooked during collecting, it is likely that it became extinct until its re-introduction.

★ Peter Skidmore recovered *B.rustica* from a pupal chamber in a pine whilst fieldwalking.

† This species was added to British list by Johnson (1966). Became extinct before its "re-introduction"?

✦ Originally identified as "Species A" by Whitehouse (1993).

APPENDICES

APPENDIX A

Classification of Rare and Scarce Coleoptera

As an aid to conservation, The Nature Conservancy Council (NCC) published in 1987 "British Red Data Books: 2, Insects" (Shirt 1987). This is a comprehensive statement on the status of most threatened insects in Great Britain, the main purpose of which is to draw attention to those species which insects whose continued survival is threatened, including those which have stable populations but occur in only a few sites. The Book contains three major categories based upon degrees of threat (RDB classifications). These categories were added to in the various reviews (e.g. Hyman, 1992, 1994) carried out by the JNCC.

Definitions

Categories 1: **Endangered (RDB1)**

Species in danger of extinction and whose survival is unlikely if the causal factors continue operating.

Category 2: **Vulnerable (RDB2)**

Species believed likely to move into the Endangered category in the near future if causal factors continue operating.

Category 3: **Rare (RDB3)**

Species with small populations that are not at present Endangered or Vulnerable, but are at risk.

Nationally Scarce

Notable A species (**NA**) are known to occur in 100 or fewer of the 3,600 ten-km squares of the Ordinance Survey National Grid in Britain; whereas Notable B species (**NB**) occur in 1000 squares.

APPENDIX B

Fieldwalking results, Hatfield Moors.

Kilham West

The western section of this area represents one of the largest of the buried forest on Hatfield Moors. Each ditch, along the whole length of the field, was surrounded by tree macrofossils and represents a high concentration of material, probably comparable with the material from Tyrham Hall Quarry. About 85-90 % of the trees are *Pinus*, the rest being *Betula*. The trees appeared to be rooted into the underlying sands and were of a considerable size. Some of the trees were clearly charred. There seemed to have been a lot of erosion of some of the surfaces, where charred material may have dropped away.

Many of the trees did not retain their bark, suggesting they had been exposed to the elements rather longer. Material from Tyrham and Thorne Moors (Goole), for example, had many trees with bark still intact. The colour of the wood was silver/white, suggesting they had been exposed to the elements for some time: many of these trees are golden when they first come out of the peat. Having discussed the area with peat workers, it appears the trees were exposed within the last year (1995). Roots of the trees were solid and sizeable, but had a good lateral root development, suggesting the trees were growing with roots spreading. Many of the trees were stumps *in situ*, rather than trunks, although there were also some very long trunks visible. There were signs of burning on many macrofossils throughout the area. Some of this was quite unusual, with charring under the roots, indicating localised burning, when trees had already fallen on their sides, either on the floor of the developing mire, or when they had been buried within the peat body. In any case, rotting wood material and peat would have made the location prone to fires. In addition to all the *Pinus* and *Betula* observed, a single *Quercus* macrofossil was identified by Gretel Boswijk, who was accompanying the author on this occasion. This was the first time *Quercus* remains have been noted on Hatfield Moors. The oak had 50 or more growth rings. It is perhaps pertinent that the location of the tree was on the present margins of the present Moors. The trees were rooted into the sand substrate and overlain by peat.

To the east of this area, the peat appeared shallower, particularly towards the direction of Lindholme island, with sand dunes protruding through the peat. Within this area an iron pan was also visible within many sections. Above the iron pan is generally a thin layer of sand (circa 5 cm.) with rootlets. Into both these deposits are rooted the remains of *Pinus sylvestris*. Directly above the sand appears to be *Sphagnum* peat, suggesting that this area

of the Moor did not go though a fen phase of bog development. Most of the tree macrofossils in this area appear to follow the distribution of the sand dunes protruding through the peat. In some of the large drainage ditches running west-east there are also deposits showing rounded pebbles and other material beneath the iron pan. It seems likely that this material marks part of the moraine represented by Lindholme island, but deposits were too shallow to impede first wind-blown sand and then peat to develop above them.

Kilham East

Fairly deep peat, *c.* 1.5-2 metres in places in the boundary ditch. The milling ditches did not reach the underlying sands, but showed the well-humified layer, suggesting the basal sands were only about 50 cms beneath the exposed sections. Sand dunes were evident in localised places. Along the side of the dike tree remains were evident about 1.20-1.30 cms from the basal sands, possibly *Pinus* or *Betula*, suggesting these trees had colonised the mire during a period of drying-out. There are also tree remains within the lower levels of the exposed peat, suggesting that at least two phases of drying had occurred in this area. Towards the southern section of Kilham East sand dunes were protruding through the peat. A section against one of these sand dunes was cleaned, showing a succession of pale sand, followed by a darker sand, with dark sand lenses, immediately above which was black, well-humified peat of about 4-5 cms. thickness, followed by less well-humified brown and then brown, largely unhumified peat. Of interest in this area was the presence of evident recurrence horizons, which appeared to follow the contours of hollows and hummocks.

Belton section 1

This is an area of abandoned cuttings which is vegetated. Visibility of this area was so poor that it was not fieldwalked.

Packards North, section 2

Ditches in this field were between 1-1.5 metres in depth, although in places as shallow as 0.50 cm Many charred trees were observed in this area. The charring observed seems superficial and patchy, although this may be related to the variable survival of charred wood on exposed macrofossils. It was not clear how long the material had been exposed to the elements, possibly one or two summers. Some of the trees indicated that they had been growing on the surface of the developing bog, possibly indicating the colonisation

of the mire surface during drier periods. This was suggested by the fact that the roots were rooted into the peat.

In the middle section of the field there were sand dunes, upon which was a concentration of *Pinus* stumps, twigs, branches and trunks, indicating that the pines had been growing on the surface of the sand dunes. In this area there was only circa 30-40 cms. of peat above the basal sands, whereas in other areas of the field peat depth was much greater, suggesting peat developing on the sand dunes was more recent compared with those areas where the sand dunes were not as elevated or within the "hollows" of the dunes. The pines are generally small, as if stressed and not as large as the ones observed in the area around Tyrham Hall Quarry.

Looking at the peat section, at the base there is the wind-blown sand, which appears to show signs of root activity. Immediately above this was recorded a very fine layer (1 cm.) of dry, well humified peaty/soil, possibly representing a "forest" soil. Above this are 2-3 cms. of *Sphagnum* peat with *Scheuzeria* rhizomes, grading into *Scheuzeria* peat. This suggests that in this area of Hatfield Moors there was no fen episode, with a transition from forest into *Sphagnum* peat. Within the underlying sands are also the remains of glacially smoothed pebbles, probably deposited when the moraine of Lindholme island was formed. These gravels become more evident the closer to Lindholme island, and the sand and gravel deposits protrude markedly in this area, with a corresponding increase in the number of trees growing on these areas. The pines show signs of charring in this area.

Packards South

The area covered by this field still contains a relatively good peat depth. In the western corner peat workers suggested there was up to 3.5 metres in depth of peat. Unfortunately, peat depths close to the terminal ditch were no-where that close. This is the area where the HAT 4 site was sampled from, but the greatest depth recoverable was about 1.5 metres of peat. Not many tree macrofossils were recorded from this field. It seems likely this is because the depth of peat remaining on the field was sufficiently deep that the basal trees were not exposed at this location. Indeed, when sampling was carried out at the HAT 4 site the section revealed the basal deposits contained the remains of both *Pinus* and *Betula*. In addition, there were no dunes protruding through the peat, upon which trees would have been able to grow. It seems likely therefore that in this area the basal sands do not form dune fields and so the palaeoforest is preserved only in the basal deposits in this area.

West Ash Dump section 1

This area was not fieldwalked as it was one of the few areas which have been returned to nature conservation and were regenerating with young *Betula* and some *Calluna*. The area was also surrounded by large ditches which at the time of visiting this area where full of water, so it was not possible to get onto the area. There were stockpiles of *Pinus sylvestris* which were piled alongside the surrounding ditch suggesting many of the tress had come from the ditch, although some many have also come off the former milling field. Given the proximity of this area to the moraine of Lindholme island, it is not surprising that there should have been a sizeable number of tree macrofossils, particularly as the morainic ridge of the Island extends into this area, making this an ideal area where *Pinus* would have lived.

West Ash Dump section 2

The southern-most part of this field was re-vegetating, so was not walked.

East Ash Dump, sections 1 & 2

East Ash Dump, section 1 contained old style, wide baulks, some 1-1.5 metres high and the area was re-vegetating with *Calluna*, Betula and a few young *Pinus*, presumably re-colonising from Lindholme island. This area presented a good sampling opportunity, but time constraints upon the project prohibited taking any further samples. However, if the area has not been stripped for milling it should present a good opportunity for sampling.

Section 2 had been completely worked out, but showed the presence of in *situ Pinus* stumps at the base of the peat, which had clearly been growing in the underlying sand. Of interest was the "ripped" nature of the stumps, with jagged edges protruding. This was a feature of many of the *Pinus* stumps observed across the Moors, suggesting that the bases of the pines had becomes disconnected from their trunks by a deterioration and rotting of the pine trunks.

New Moor North

This area was re-vegetating with *Betula* and *Calluna* and had clearly been cut for peat using the old style "block cutting" technique, but due to the vegetation on site could not be fieldwalked. On a subsequent trip several years later it was noted that the area had been cleared for peat milling.

New Moor South

This area had been cleared of vegetation for milling recently, but unfortunately contained no drains (except periphery ones) which could be walked.

Porters Drain

This large drain running west-east of the eastern side of Hatfield Moors forms a major boundary in this part of the Moor. It a major and deep (*c.* 3 metres deep) ditch, with a good peat succession. Unfortunately, the ditch contained too much water to sample safely. Tree remains which had come out of the drain were evident beside the drain and tree macrofossils were evident in the exposed sections. The area to the south of the drain had only been recently cleared of vegetation prior to milling and contained no drains, so it was not fieldwalked. In a subsequent visit several years later ditches had been installed, but it was not fieldwalked.

Lindholme Island

The island was not systematically fieldwalked, none of the fields were under cultivation at the time of the field work. However, the area was walked by the Humber Wetlands Team. In addition, the author walked around the area covered by the Island and made several records. A quarry close to Lindholme provided the opportunity to photograph an exposed stratigraphic section through the moraine. The section was about 2.5 metres deep, showing the top soil grading into aeolian sands. Beneath this unit was a matrix of rounded pebbles grading into heavier rounded pebbles, mostly of sandstone. The pebbles vary in size and are mixed. This material represents material which was deposited at the end of the Devensian, when the ice sheet surged into the area, creating the moraine which is now Lindholme Island.

Apart from a central area which is dominated by grassland, the island is composed of mixed woodland, with some mature *Quercus*, relatively young *Betula* woodland and *Pinus sylvestris* in areas, generally in isolated stands. *Calluna* and *Pteridium* form the understorey. Towards the margin of the island, there are deeper deposits of peat and the growth of *Sphagnum*. Indeed, the northern part of Lindholme has an active catotelm (Howes, *pers. comm.*). A drainage ditch surrounds Lindholme island, which most of the time contains water. One section was observed, which was dry, with a depth of about 1.75 cms. of peat. From base to the top, the stratigraphy showed sand at the base, followed by sandy peat, followed by a layer containing *Pinus sylvestris*. Above this layer was well-humified peat, followed by layers of unhumified and humified peat.

Unfortunately, the stratigraphy was not measured on this occasion, but these observations are included here as a record.

On the northern-western side of the island were the remains of pine macrofossils which had evidently come from the drainage ditch which surrounds the island; the size of the macrofossils was small, displaying stunted and contorted root systems, suggesting the trees had died at a young age and were living in stressful conditions; the wide rooting system of the roots suggests this was probably related to increasing water table in the area. None of the macrofossil displayed any signs of charring.

Tyrham Hall Quarry

An area which was being worked for peat was investigated, approximately about 300m wide by 400 m in length. The area from which samples were removed contained a large quantity of tree macrofossils, mainly *Pinus sylvestris*, some *Betula*, and some scattered *Quercus* trunks. The peat was still in a reasonably wet state, so much of the material was in excellent condition. The area was walked, and some observations regarding the state of the trees was noted. Some of the trees had very wide root stumps, with quite substantial sized roots. In one example, the width of the roots, from one end to the other, was about 2.5m across, with the main part of the trunk probably about 55cm. in diameter. In some cases, the pines had been clearly rooted into the underlying aeolian sands, which was still adhered to the root formation, together with part of the iron pan which is visible across certain areas of Hatfield moors, most notably on its north-western side. There were a substantial number of tall, substantial straight-growing trees, and many appeared to have been growing in good conditions, an impression which is corroborated by the dendrochronological data carried out by Gretel Boswijk (1998). The density of trees in the area was so large that there appeared to be several generations of trees here (i.e. several hundred years), an impression which again is corroborated by the dendrochronological data.

Another pine tree trunk was very straight in growth, about 7.5 metres long, and was riddled with insect flight holes. These flight holes in some cases were very large, indicating that the pine had been quite badly attacked by insect activity in the past; the state of the holes indicated that the insect attack had not occurred recently, and most likely the tree had been attacked at some stage before being submerged by the acidic conditions of the mire at Hatfield Moors. Some of the exit/entry holes were about 3.5 cms. in diameter, with others varying between 3 & 2 cm. in diameter, possibly created by members of the Cerambycid family, such as the genus *Rhaghium*. There was also some

oak growing on the site, which appeared to have been growing together with the pine trees, but appear to have been much smaller in size in comparison with ones recorded from Thorne Moors. To provide some measure of the density of the tree macrofossil remains, an area roughly measuring about 26m E-W by 18m N-S contained thirty tree. Another area examined, roughly 100m X 100m contained about 52 stumps, many of which were large in size.

Many of the trees had visible signs of charring, with charcoal sealed beneath the peat, on the surface of the wood. One large pine was examined which was charred along one side, but its other side still retained its bark, uncharred. This circumstantial evidence would suggests that the tree was probably burnt after death, when it was lying on its side; it seems unlikely that it had been burnt whilst it was still alive and standing. It should be noted that charring on many of these trees is often difficult to identify, as the friability of the charcoal causes it to drop away from the tree macrofossils when exposed by the digging machines. All of the samples which were subsequently processed contained large fragments of charcoal.

APPENDIX C

Sample and processing details

SAMPLE DETAILS: HATFIELD 2, (HAT 4), south Hatfield Moors.

Processing Details

Sample No.	**29**	**28**	**27**	**26**	**25**
Context	150-155 cms.	145-155 cms.	140-145 cms.	135-140 cms.	130-135 cms.
Soil description	Very well humified, amorphous, dark brown/black peat, some *Phragmites* and wood remains.	Black, well humified brushwood peat, including many wood fragments of *Pinus* and *Betula.*	Dark brown/black, moderate to well humified brushwood peat, with *Pinus*, *Betula* and ? *Quercus* frags.	Well humified *Sphagnum* peat, with wood remains, *Pinus*, *Betula* and ? *Quercus.*	Dark black/brown, well humified brushwood peat, with evident *Betula* remains.
Sample volume	6 litres	6 litres	7 litres	7 litres	7 litres
Volume processed	3 litres	3 litres	3 litres	3 litres	3 litres
Volume of flot	30 ml.	17 ml.	18 ml.	15 ml.	20 ml.

APPENDIX D

Identification problems

General identification problems

Identification of the aquatic genus *Hydroporus* to species is notoriously difficult. In some cases, successful identification was carried out to species level. However, this was not always possible, although it was clear that different taxa were present in the assemblage. In such cases, a note was made as to how many species were represented. In addition, as the expertise of the researchers' identification skills increased identification of this taxon was made to species level more frequently. Much time was invested in attempting to successfully identify this genus, since it can yield interesting information regarding water quality, acidity and a range of other factors. It was noted that whereas micro-sculpture is a useful attribute to aid identification, the shape of the angle of the shoulder on the underside of the elytra is a good diagnostic feature for speciation. This is an attribute which is not picked out in any keys, but proved a useful way of separating out taxa and identifying different species.

Cyphon is another genus which is difficult to identify. These beetles have very fragile elytra which can often get torn during processing. It was decided from the outset to record these fragments to genus, except for one species, *Cyphon padi*, which has a distinctive macula on the elytra. Other genera which were not pursued to species level were individuals of the genus *Stenus* (except those species with a distinctive orange macula) and the mould feeders *Corticaria*.

The hydrophilid, *Hydreana britteni/riparia* was a common fragment within many of the samples. The diagnostic sclerite for the successful identification of this species is its thorax (Jäch, 1988). In many cases, only elytra survived and attempting to separate the two species on this body part was problematic. Where possible, separation of the two species was attempted. Where this was not possible, the sclerites were recorded as *Hydreana britteni/riparia*. Another pair of species difficult to separate were the reed beetles *Plateumaris sericea/discolor*. Separation of these two species upon elytra is virtually impossible, although they can be separated on thorax and occasionally, on heads. Separation of these two taxa is quite important, as the former is an indicator of non-acidic mire conditions (fen) and the latter of acid wetlands (ombrotrophic mire). Where separation was not possible, individuals were recorded as *P. sericea/discolor*. The ground beetle *Pterostichus nigrita/rhaeticus* was identified to this species category, as both species are easily confused and are only safely separated on genitalia (Luff, 1990).

Specific identification problems relating to particular assemblages.

Hatfield 1

Few identification problems were encountered. Sample 18 contained more poorly preserved material compared with 17, originating from the black, very amorphous basal peat which is common across many areas of Hatfield Moors. A greater proportion of taxa could only be identified to genus rather than species, although the majority of fossils were identified to species. Additional time was spent in the identification of the non-British species, such as *Rhyncolus sculpturatus*, identified on the basis of its elytra, through the use of a new key to this genus devised by the author (Appendix D). Identification was also confirmed by comparison with a named specimen at Manchester Museum. *Rhyncolus elongatus* was identified in the same way. *Prostomis mandibularis* was another non-British species recovered and identified on the basis of its thorax and named characteristics within Porta (1929) and comparison with a named specimen at Manchester Museum.

Hatfield 2

Beyond the identification problems already discussed in section 5.4, several other taxa were problematic. The extinct *Tenebrioides fuscus* was identified on the basis of the elytra recovered and named morphological characteristics in Vogt (1967a). However, it could not be compared with a named specimen, although a special trip to the Coleoptera collection at the British Museum was undertaken. There are apparently no known specimens of *Tenebrioides fuscus* in England.

The other extirpated taxon recovered was a single *Rhyncolus punctulatus* identified on its elytra, on the basis of a new key (Appendix D). Confirmation was made by comparison with a named specimen at Manchester Museum. A number of individuals of *Ostoma ferruginum* were also recovered from this sequence. Initially these fossils were thought to be *Zimioma grossum*, a closely allied non-British species. However, on closer inspection it was found that the fossils were *Ostoma*, based upon the setiferous punctures upon the "ribs" of the elytra, which *Z. grossum* does not have. Comparison was also made with a named specimen at Manchester Museum. A thorax of the Colydiid *Synchita humeralis* could not be matched against material at Doncaster Museum, but was identified by Colin Johnson (Manchester). The separation of *Melasis buprestoides* and *Isorhipis melasoides* was occasionally problematic, as the diagnostic feature used to separate these two species is the elytral apex, which was not always available (e.g. sample 27).

Members of the family Scolytidae were identified through use of keys and the reference collection at Manchester Museum.. Several specimens proved to be problematic to identify and were eventually assigned to the genus *Hylesinus/Leperisinus* A. The fossils are reproduced in Figure 6.6. Part of the problem identifying these fossils related to the presence of small "spines" on the top part of the elytra, near the central suture. Since recent specimens are still covered with setae it is difficult to see any spines, although they should still show through. However, none of the reference material satisfactorily matched the fossil material. Keys were also utilised to identify the fossil, but none of the descriptions appeared to match the fossil. The fossils seem to be closely related to the genera *Hylesinus* and *Leperisinus*.

Lindholme A

Few identification problems were encountered. The non-British fossil *Chryptolestes corticinus* was identified on the basis of its elytra. This was carried out through the use of taxonomic keys in Freude, Harde & Lohse (1967) and Porta (1929) as well as comparison with a named specimen at Manchester Museum and confirmed by Colin Johnson. All members of the Scolytidae were taken to Manchester Museum for identification.

Lindholme B

The standard of preservation in these samples was generally good, allowing identification to species in the majority of cases. All samples scored 4 (Good) on the Preservation Index for Coleoptera remains. There were no significant identification problems. One of the most important species recovered was the ground *Bembidion*? *humerale*. Unfortunately, its elytral apex was missing, a diagnostic element for this species. This species has a macula on the shoulder, but not the apex; other species of *Bembidion* with shoulder markings have corresponding markings on the elytral apex. The identification of the sub-fossil was based upon the shape of the macula and of the shoulder, which closely matched modern specimens of this species. These characters were also checked against other species in the genus, but the closest identification was clearly *B. humerale*. In the absence of the apex, the identification remains tentative.

Pterostichus augustata was identified on the basis of a pronotum and confirmed by a Carabidae specialist, Brian Eversham. There were two other species this specimen could have been confused with, *P. oblongopunctatus* and *P. adstrictus*, but extensive comparison with specimens of all species confirms the identification. This was on the

basis of the relatively small and narrow thorax; it was heavily punctate at the base; strongly sinuated at the sides; the base was strongly oblique and the margin was moderately wide throughout. Since this species is regarded as an introduction early this century, the identification of this specimen had to be secure, given the biogeographic implications of its presence.

Tyrham Hall Quarry

Most of the material from these contexts were in excellent condition. In particular material from sample 1 contained material in a superb state of preservation, with many individuals virtually still intact. This facilitated the process of identification. All members of the Scolytidae were taken to Manchester Museum for identification. The non-British fossils recovered (members of the genus *Rhyncolus* and *Prostomis mandibularis*) were identified on the basis of European keys and compared against a named specimen at Manchester Museum. The key devised by the author (Appendix D) was also used to identify the *Rhyncolus* species.

Goole Moors (Thorne Moors), *Quercus/Pinus* sequence

The only specimen which created any problems was from sample 19, Pycnomerus tenebrans, as only the apex of the elytra was available for identification. The specimen was taken to the British Museum and compared with a range of species of this genus. However, this species is extremely distinctive and has upstanding striae, curved, with punctures on the striae. It is very different from the British species, *P. fuliginosus*, which is dull, with different striae and much bigger punctures on the striae.

Hayfield Lodge Farm, Rossington

The extensive range of Scolytids recovered from this succession were all taken to Manchester Museum for identification. The non-British *Rhyncolus punctulatus* was identified at Manchester through comparison with a named specimen and key characteristics.

A head of *Agelastica alni* was identified by P. Skidmore for the author. The fossil was also taken to Manchester Museum for comparison with a range of specimens, since the Doncaster collection contained just one specimen of this rare species. The range of reed beetles of the genus *Donacia* proved a challenge to identify. This was done through patient comparative work of modern specimens. However, the information gained from these aquatic vegetation beetles was worth the time expended during identification.

Table 9.2; List of species included in CANOCO analysis, including abbreviated names which appear in plots (N.B. Species are not in taxonomic order. Their order is determined by the number of samples each species occurred in, sorted in numerical order).

Species	Abbreviated name
Bradycellus spp.	Bradyc
Ilybius aenescens Thom.	Ilaenesc
Ilybius spp.	Ilybius
Agabus/Ilybius sp.	Ag/Il
Colymbetes fuscus (L.)	Colfusc
Enochrus spp.	Enochrus
Agathidium sp.	Agath
Xantholinus linearis (Ol.)	Xanlin
Atrecus affinis (Payk.)	Atraffin
Othius myrmecophilous Kies.	Othiusmy
Erichsonius cinerescens (Grav.)	Erichscin
Mycetoporus sp.	Mycetop
Atomaria spp.	Atomaria
Phalacrus caricis Strm.	Phalcar
Cerylon histeroides (F.)	Ceryhist
Dryocoetinus villosus (F.)	Dryovill
Ceutorhynchus spp.	Ceutorhy
Trechus obtusus Er./ *4-striatus*	Tobtusus
Bradycellus harpalinus (Serv.)	Bradyhar
Hydroporus longulus Muls.	Hylong
Agabus affinis (Payk.)	Agaffin
Helophorus spp.	Heloph
Silpha atrata L.	Silphatr
Stenus kiesenwetteri Rosen.	Stkiesen.
Paederus spp.	Paederus
Gabrius spp.	Gabrius
Bryaxis curtisi (Leach)	Brycurt
Pselaphus heisei (Hbst.)	Pselheis
Denticollis linearis (L.)	Dentlin
Melasis buprestoides (L.)	Melasis
Chrysomela aenea L.	Chryaen
Altica britteni Sharp	Altbritt
Altica sp.	Altica
Phyllobius sp.	Phyllob
Dryophthorus corticalis (Payk.)	Dryocort
Hydroporus gyllenhali Schdte.	Hygyll
Hydraena testacea Curt.	Hydrtest
Stenichnus collaris (Mull.)	Stencoll
Lathrobium rufipenne Gyll.	Lathrufi.
Lathrobium longulum Grav.	Lathlong
Ochthephilum fracticorne (Payk.)	Ochfract
Dalopius marginatus (L.)	Dalomarg
Scolytus ratzeburgi Jans.	Scolratz
Tomicus piniperda (L.)	Tompini

Rhyncolus sculpturatus Walt.	Rhynscul
Lathridiidae indet.	Lathrid
Bembidion spp.	Bembid
Cercyon spp.	Cercyon
Lathrobium terminatum Grav.	Latherm
Rhamphus pulicarius (Hbst.)	Rhpulic
Pterostichus spp.	Pterost
Hydraena britteni Joy	Hydbrit
Ochthebius spp.	Ochtheb
Limnebius aluta Bed.	Limaluta
Coelostoma orbiculare (F.)	Coelorbi
Enochrus affinis (Thun.)	Enocaff
Olophrum fuscum (Grav.)	Olofusc
Corticaria spp.	Cortic
Rhyncolus elongatus Gyll.	Rhynelon
Dyschirius globosus (Hbst.)	Dyscglob
Philonthus/ Quedius spp.	Phil/ Qu
Grynobius planus (F.)	Gryplan
Scolytidae gen. et sp. indet.	Scoly
Quedius spp.	Quedius
Microcara testacea (L.)	Micrtest
Plateumaris spp.	Plateum
Rhynchaenus rusci (Hbst.)	Rhyrusci
Bradycellus ruficollis (Steph.)	Bradrufi
Pterostichus minor (Gyll.)	Ptminor
Hydroporus tristis (Payk.)	Hytrist
Hydroporus melanarius Strm.	Hymel
Acidota crenata (F.)	Acrenata
Lathrobium fulvipenne (Grav.)	Lathfulv
Rhynchaenus quercus (L.)	Rhyquerc
Agonum obscurum (Hbst.)	Agobscur
Hydroporus scalesianus Steph.	Hyscales
Lesteva heeri Fauv.	Lestheer
Apion spp.	Apion
Rhyncolus chloropus (L.)	Rhychl
Cercyon convexiusculus Steph	Cercconv
Megasternum obscurum (Marsh.)	Megaobsc
Lathrboum brunnipes (F.)	Lathbrun
Philonthus spp.	Philont
Bryaxis bulbifer (Reich.)	Bryabulb
Aphodius spp.	Aphodius
Rhynchaenus spp.	Rhynchae.
Ochthebius minimus (F.)	Ochtmin
Hydrobius fuscipes (L.)	Hydfusc
Plateumaris discolor (Panz.)/ *sericea* (L.)	disc/ser
Plateumaris sericea (L.)	PlatSer
Agabus bipustulatus (L.)	Agbip
Micrelus ericae (Gyll.)	Micreric
Bryaxis spp.	Bryaxis

Plateumaris discolor (Panz.)	Platdisc
Agabus spp.	Agabus
Agonum fuliginosum (Panz.)	Agonfuli
Anacaena globulus (Payk.)	Anacglob
Cyphon padi (L.)	Cyphpadi
Olophrum piceum (Gyll.)	Olopic
Pterostichus nigrita (Payk.) / *rhaeticus*	Ptnigrit
Lathrobium spp.	Lathrob
Pterostichus diligens (Strm.)	Ptdilig
Aleocharinae gen. et sp. indet.	Aleoch.
Stenus spp.	Stenus
Cyphon spp.	Cyphon
Hydroporus spp.	Hydrop
